UNIV OF CALIF
MEDICAL SCHOOL

INDEX TO VOLUME 26

A

Abdominal injuries, 529
A and B substances, Plasma and serum toxicity due to, 1056
Abdominal pain, 61
Abnormal uterine bleeding in adolescence, 961
Acute obstruction of the bowel, 1009
Acute suppurative otitis media—a reconsideration, 257
Adson, Alfred W.: Evolution of neurosurgery, 66
Adson, Alfred W.: The doctor of medicine and his responsibility, 352
Adson, Alfred W., and Baker, George S.: Treatment of craniocerebral injuries in modern warfare, 282
Adults, normal, Nutrition in, 610
Advances in radiology in the past quarter-century, 87
Aerophagia, 350
Aged, General care of the, 876
Aged, Nutritional management of the, 881
Aged, Surgical treatment of the, 884
Agranulocytosis associated with sulfadiazine therapy (case report), 898
Allergy, extreme, to bee body and bee venom, Successful treatment of (case report), 1061
Allison, R. G.: Advances in radiology in the past quarter-century, 87
Anesthesia, intravenous, Newer trends in, 349
Anesthesia, Spinal—important principles, 346
Anesthesia, spinal, Neurological complications associated with, 339
Anesthesiology, Twenty-five years of "Minnesota Medicine" and of, 57
Anesthetic, spinal, Injury to spinal cord and meninges from (abstract only), 491
Aneurysm, Congenital arteriovenous (case report), 627
Animals, Virus diseases of, 604
Appendicitis, acute, Nonclosure of wounds in, and the use of the Gibson-Mickulicz tampon, 651
Appendicitis, Pain as a symptom in, 622
Arbeiter, Herbert I., and Levine, Milton Gjelhaug: Reinfection with pneumococcus meningitis (case report), 1065
Arteriovenous aneurysm, Congenital (case report), 627
Arthur, Grace: Delayed speech from the standpoint of a psychologist, 369
Aseptic gastric resection for ulcer and carcinoma, 833
Athens, A. G.: Visual malingering, 266
Atypical pneumonia, 337
Auricular fibrillation, Pathologic changes in the auricles in, associated with hypertension, 699

B

Baker, A. B., and Kamman, Gordon R.: Damage to the spinal cord and meninges following spinal anesthesia—a clinico-pathological study, 786
Baker, George S., and Adson, Alfred W.: Treatment of craniocerebral injuries in modern warfare, 282
Baker, Jeannette: Preparing the child for school, 1041
Barnes, Arlie R.: Recent advances in our knowledge of coronary sclerosis and its bearing on the clinical management of patients, 863
Barron, Moses: The medical management of peptic ulcer (abstract), 205
Baxter, Stephen H.: The physician in civic life, 521
Bee body and bee venom, Successful treatment of extreme allergy to (case report), 1061
Bell, C. Curry: Compression fractures of the spine, 687
Beneficial effect of urea in topical sulfonamide therapy, The, 276
Benjamin, A. E.: Acute obstruction of the bowel, 1009
Biceps brachii, Rupture of the long head of the, 834
Biceps muscle of the arm, Rupture of the long head of the, 836
Bile, White, 955
Bleeding, Abnormal uterine, in adolescence, 961
Blood count, routine, in the newborn, Practical applications of a, 779
Blood, The discovery of the pulmonary circulation of the, 1054
Blumenthal, Jacob S., and Wetherby, Macnider: Vitamin A in the treatment of hypertension, 370
Boehrer, John J.: Nutrition in normal adults, 610
Boleyn, E. Sydney: Reminiscences, 99
Bowel, Acute obstruction of the, 1009
Boyd, W. L.: Virus diseases of animals, 604
Boynton, Ruth E.: Diagnosis of early tuberculosis among University students, 439
Bratrud, Arthur F.: Nonclosure of wounds in acute appendicitis and the use of the Gibson-Mickulicz tampon, 651
Bratrud, Theodor E., and Flink, Edmund B.: Agranulocytosis associated with sulfadiazine therapy (case report), 898
Bronchial occlusion, Roentgenologic observation on (abstract), 1097
Brown, W. H., and Jenkinson, E. L.: The differentiation of endometriosis and carcinoma of the sigmoid colon, 773
Brucellosis, Chronic or recurrent, 568
Bulkley, Kenneth: Unusually severe facial injury, 737
Burch, Frank E.: Malignant melanomas of the uvea and their prognosis, 208
Burns, Treatment of, 534

Book Reviews

American Medical Association: Reports of the Council on Pharmacy and Chemistry, 750
Anderson, Dwight, and Baylous, Margaret: When doctors are rationed, 313
Anderson, W. A. D.: Synopsis of pathology, 397
Barzilai, Gemma: Atlas of ovarian tumors, 498
Brawner, James N.: The mind and its disorders, 221
Colwell Publishing Co.: Dr. Colwell's daily log, 1022
Compere, Edward L., and Banks, Sam W.: Pictorial handbook of fracture treatment, 1106
Geist, Samuel H.: Ovarian tumors, 397
Hamilton, Burton E., and Thomson, K. Jefferson: The heart in pregnancy and the child-bearing age, 297
Herrold, Russell D.: Chemotherapy of gonococcic infections, 497
Jackson, Arnold S.: The answer is—Your nerves, 220
Kilduffe, R. A., and DeBakey, Michael: The blood bank and the technique and therapeutics of transfusions, 221
Levine, Maurice: Psychotherapy in medical practice, 313

Titus, Paul: Atlas of obstetric technique, 1022

Trueta, J.: The principles and practice of war surgery, 667

Year Book Publishing Co.: The 1942 Year Book of general medicine, 313

C

Calvin, Arthur M.: Group hospitalization, 104

Camp, Walter E.: Prognosis of malignant melanomata of the uvea from the standpoint of pathogenesis, cytology and fiber content, 210

Carcinoma, Endometriosis and, of the sigmoid colon, The differentiation of, 773

Carcinoma of the lung, 1046

Carcinoma, Primary bronchiogenic, 90

Carcinoma, ulcer and, Aseptic gastric resection for, 833

Carey, James B.: Changes in the gastric mucosa related to disease, 656

Carroll, W. C.: A deodorant for colostomies, 709

Changes in the gastric mucosa related to disease, 656

Chatterton, C. C.: Fractures of lower end of radius and ulna, 697

Chest conditions simulating tuberculosis, 430

Child, Feeding the, 1039

Child, Preparing the, for school, 1041

Children, Emotional disturbances of, in wartime, 1044

Chronic or recurrent brucellosis, 568

Cilia, Loss of, in the respiratory tract and its relation to death from respiratory diseases, 272

Circulation, pulmonary, of the blood, The discovery of the, 1054

Civic life, The physician in, 521

Clagett, O. Theron: Surgical treatment of the aged, 884

Clark, William G., and Strakosch, Ernest A.: The beneficial effect of urea in topical sulfonamide therapy, 276

Collapse therapy in treatment of pulmonary tuberculosis, 428

Collins, Arthur N.: Transurethral resection, 782

Colon, sigmoid, The differentiation of endometriosis and carcinoma of the, 773

Colostomies, A deodorant for, 709

Common duct repair by means of a vitallium tube (case report), 1064

Compression fractures of the spine, 687

Congenital arteriovenous aneurysm (case report), 627

Conjunctivitis, Staphylococcic, 263

Connor, Charles E.: Acute suppurative otitis media—a reconsideration, 257

Corneal lesions, The diagnosis of, 243

Coronary disease, 33

Coronary sclerosis, Recent advances in our knowledge of, and its bearing on the clinical management of patients, 863

Coventry, W. A.: The progress of obstetrics during the past twenty-five years, 84

Craniocerebral injuries in modern warfare, Treatment of, 282

Crow, E. R.: Chest conditions simulating tuberculosis, 430

Crowell, Bowman C.: The influence of war on medicine, 795

Culligan, John M., and Soltman, D. Jack: Trauma of the spleen, 710

Culligan, L. C.: Aseptic gastric resection for ulcer and carcinoma, 833

Curare, Use of, in metrazol treatment of psychoses, 1052

Cysts, Enterogenous, of the rectum, 1008

Clinical-Pathological Conference

Acute degeneration of the liver; bronchopneumonia; acute esophagitis; jaundice, 106

Acute jejunal diverticulitis; generalized peritonitis; bronchopneumonia, 191

Aneurysm of arch of aorta; syphilitic aortitis; bilateral bronchopneumonia, 1003

Carcinoma of papilla of Vater; jaundice; gastric and duodenal ulcers; urethral stricture; bilateral hydronephrosis; syphilitic aneurysm of aorta, 897

Carcinoma of rectum with metastasis to liver; edema of lungs; bilateral hydrothorax, 715

Chronic equine encephalitis, 445

Chronic glomerulonephritis; solitary kidney; uremia; congenital absence of uterus, Fallopian tubes and vagina; bronchopneumonia, 289

Chronic lymphatic leukemia; chronic atrophic gastritis; macrocytic anemia, 1061

Essential hypertension with uremia; congenital polycystic kidneys; multiple cerebral hemorrhages; hypertrophy of heart; bronchopneumonia, 626

Lobar pneumonia; old valve defects; acute bacterial endocarditis; adherent pericardium; coarctation of the aorta, 372

Mycosis fungoides with involvement of skin, right lung and liver; bronchopneumonia; right hydrothorax, 544

Tuberculous pericarditis with effusion; bilateral pulmonary tuberculosis; chronic passive congestion of liver; adenomatous goiter; old tuberculous arthritis of left hip; scoliosis of lumbar spine, 804

Communications

Cahal, Mac F., 1088

Garland, L. Henry, 1088

Pryor, Mrs. Genevieve J., 134

Rigler, Leo G., 1087

D

Damage to the spinal cord and meninges following spinal anesthesia—a clinico-pathological study, 786

Davis, William: Medicine in Minnesota sixty years ago, 97

Deafness, Eustachian tube function and, 250

Delayed speech from the standpoint of a psychologist, 369

Deodorant for colostomies, A, 709

Development of clinical pathology as a specialty, The, 52

Diagnosis of corneal lesions, The, 243

Diagnosis of early tuberculosis among University students, 439

Lowered resistance to tuberculosis... How to watch for it!

TUBERCULIN PATCH TEST (Vollmer)
Lederle

WAR ITSELF MAY BE VIEWED as a cyclic epidemic that brings in its train a whole series of infections to prey upon the exhaustion of its victims. *Malnutrition*, *overcrowding*, *overactivity* and *undue exposure to cold and wet* combine to harass civilians and combatants alike when war is fought as much upon the home front as in the combat zone.

When to these factors of lowered resistance is added contact with clinical tuberculosis, the stage is set for rapid spread of the disease among the susceptible elements of the population. Thus in war the secular downward trend of tuberculosis flattens out and may exhibit a war-time ascent.

The "TUBERCULIN PATCH TEST (Vollmer) *Lederle*" has facilitated large-scale case-finding surveys by school and public health authorities[1,2] throughout the United States. It has the advantages of *ease of application*, *reliability* and *painlessness*.

Supplied in packages of
1, 10 and 100 tests

NOW IS THE TIME FOR EVERY COMMUNITY TO START A CASE-FINDING CAMPAIGN TO HALT THE RAVAGES OF THIS COMMON FOE!

Specify **Lederle**

LEDERLE LABORATORIES, INC., 30 Rockefeller Plaza, New York, N. Y.

INCONCLUSIVE symptomatology constantly challenges the physician's resources. If the patient smokes, a check-up on nicotine intake may be in order.* But this is a problem in itself, considering the reluctance of smokers to accept adjustments of tobacco usage.

Slow-burning Camel cigarettes provide an answer. They are the voluntary choice of millions and millions of smokers who appreciate distinctive mildness and mellow flavor, Camel's famous "pleasure factor." Your patient's enthusiastic acceptance of Camels will help to assure more reliable data for case histories, a big advantage when analyzing such cases by groups.

CAMEL

costlier tobaccos

The swaddled infant pictured at right is one of the famous works in terra cotta exquisitely modeled by the fifteenth century Italian sculptor, Andrea della Robbia. In that day infants were bandaged from birth to preserve the symmetry of their bodies, but still the gibbous spine and distorted limbs of severe rickets often made their appearance.

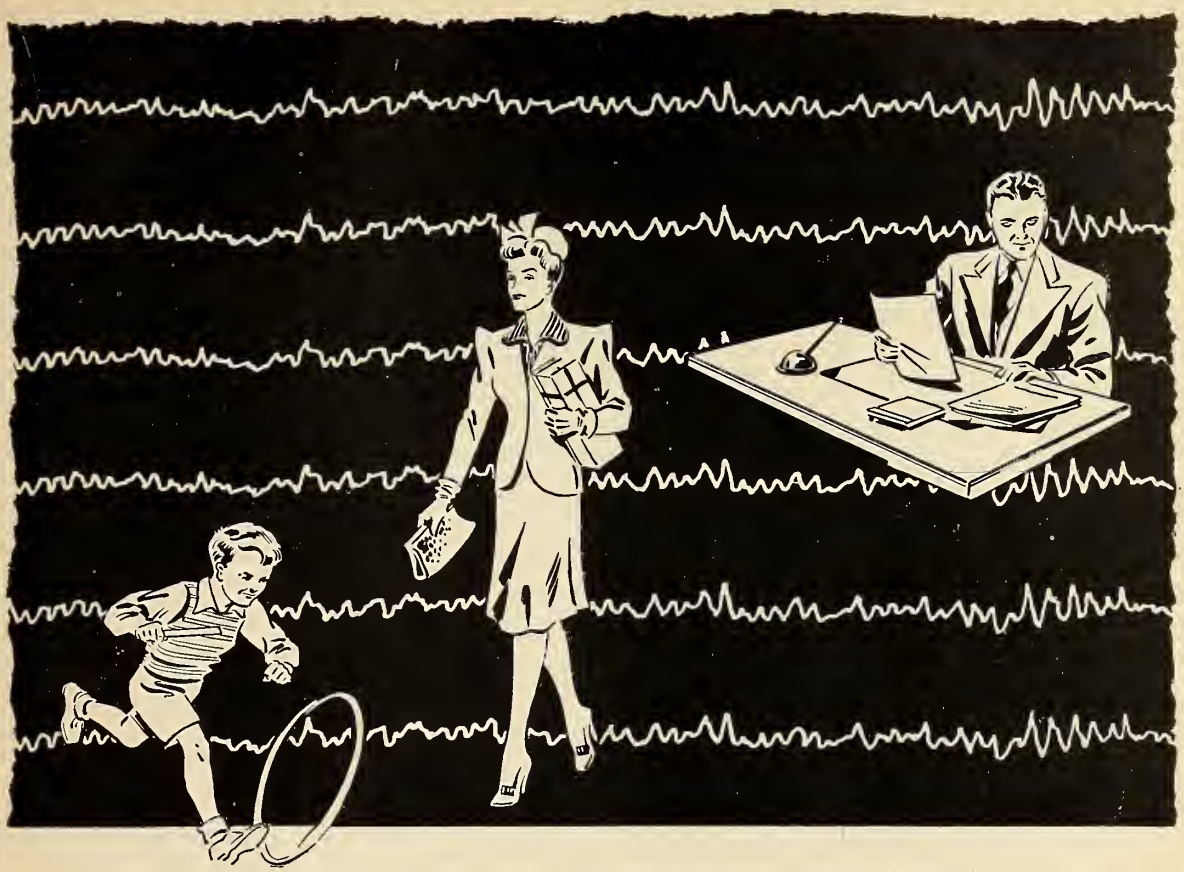
A bambino from the Foundling Hospital, Florence, Italy,—A. della Robbia

Glisson, writing in 1671, described an ingenious use of swaddling bands — "first crossing the Brest and coming under the Armpits, then about the Head and under the Chin and then receiving the hands by two handles, so that it is a pleasure to see the Child hanging pendulous in the Air . . . This kind of Excercise . . . helpeth to restore the crooked Bones. . . ."

STRAPPED FOR RICKETS

SWADDLING was practised down through the centuries, from Biblical times to Glisson's day, in the vain hope that it would prevent the deformities of rickets. Even in sunny Italy swaddling was a prevailing custom, recommended by that early pediatrician, Soranus of Ephesus, who discoursed on "Why the Majority of Roman Children are Distorted."

"This is observed to happen more in the neighborhood of Rome than in other places," he wrote. "If no one oversees the infant's movements, his limbs do in the generality of cases become twisted. . . . Hence, when he first begins to sit he must be propped by swathings of bandages. . . ." Hundreds of years later swaddling was still prevalent in Italy, as attested by the sculptures of the della Robbias and their contemporaries. For infants who were strong Glisson suggested placing "Leaden Shooes" on their feet and suspending them with swaddling bands in mid-air.



How amazed the ancients would have been to know that bones can be helped to grow straight simply by internal administration of a few drops of Oleum Percomorphum. What to them would have been a miracle has become a commonplace of science. Because it can be administered in drop dosage, Oleum Percomorphum is especially suitable for young and premature infants, who are most susceptible to rickets. Its vitamins derived from natural sources, this product is rich in vitamins A and D. Important also to your patients, Oleum Percomorphum is an economical antiricketic.

EXIGENCY OF WAR

Oleum Percomorphum 50% is now known as Oleum Percomorphum 50% With Viosterol. The potency remains the same; namely, 60,000 vitamin A units and 8,500 vitamin D units per gram. It consists of the liver oils of percomorph fishes, viosterol, and fish liver oils, a source of vitamins A and D in which not less than 50% of the vitamin content is derived from the liver oils of percomorph fishes (principally Xiphias gladius, Pneumatophorus diego, Thunnus thynnus, Stereolepis gigas, and closely allied species).

The Moving Finger Writes

OF MORE NORMAL, HAPPIER PEOPLE

THE oscillating "finger" of the electroencephalograph, recording abatement of abnormality of brain waves, tells but a part of the story of epilepsy treatment with Dilantin+ Sodium. Fewer and less severe seizures, more normal social and economic life have been observed in many thousands of epileptic patients receiving this modern anticonvulsant.

Dilantin Sodium possesses "many advantages" in the control of epileptic convulsions.[1] For one thing it is, in many cases, superior in anticonvulsant effectiveness to phenobarbital or bromides, and—highly important—it is practically non-hypnotic. The inclusion of Dilantin Sodium (diphenylhydantoin sodium) in the new U.S.P. XII speaks volumes for its therapeutic importance.

Safeguarding

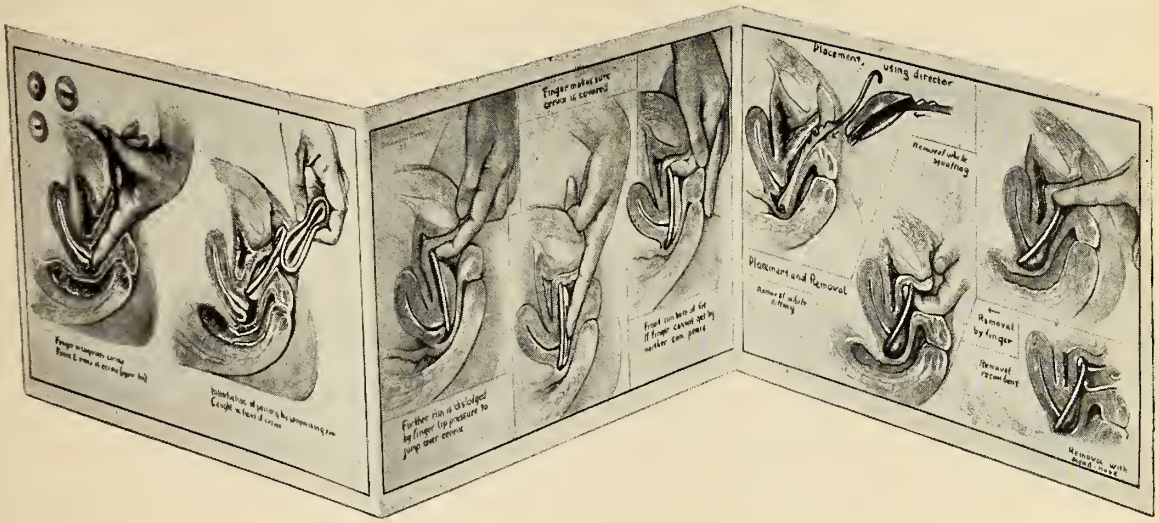
YOUR USE OF

BENZEDRINE SULFATE TABLETS

Any potent drug should be administered under medical supervision, and Benzedrine Sulfate* is no exception.

In medical literature, the majority of the reports of undesirable reactions attributed to Benzedrine Sulfate have been traceable to cases of indiscriminate or unsupervised use. This is equally true of the often magnified and sensational reports in the lay press.

Obviously, these unfavorable reports greatly retarded the wider clinical use of this valuable therapeutic agent. From the very beginning, Smith, Kline & French Laboratories—as a matter of business judgment, to say nothing of ethical considerations—did what it could to keep Benzedrine Sulfate solely in the hands of the medical profession.



But our own unaided efforts never met with complete success. And, understandably concerned over the possibility of self-medication, certain physicians hesitated to employ Benzedrine Sulfate therapy.

However, when the Federal Food, Drug & Cosmetic Act of June, 1938, became effective, we immediately put Benzedrine Sulfate in the category of drugs to be sold on prescription only. The Act is strictly enforced and is supplemented by similar legislation in many states. Today, as a result, the physician can prescribe Benzedrine Sulfate, secure in the knowledge that there is little likelihood of its abuse.

HERE ARE THE FACTS, TO DATE, ON SMOKING:

IN 1933: Because of a new method of manufacture, PHILIP MORRIS introduced the first drastic improvement in cigarette manufacture, accompanied by *a definite improvement in effect on smokers.*

UP TO 1943: PHILIP MORRIS have shown the greatest percentage of increase in sales of *any cigarette.*

THE REASON: PHILIP MORRIS are *different* from other cigarettes. Repeated tests* have proved their individual method of manufacture makes them *definitely and measurably less irritating to the smoker's nose and throat.*

YOUR OWN CHECK-UP will quickly *confirm* that statement. Why not try PHILIP MORRIS on your patients who smoke . . . and see the results for yourself?

PHILIP MORRIS

PHILIP MORRIS & CO., LTD., INC.

* *Laryngoscope, Feb. 1935, Vol. XLV, No. 2, 149-154; Laryngoscope, Jan. 1937, Vol. XLVII, No. 1, 58-60*

TO PHYSICIANS WHO SMOKE A PIPE: We suggest an unusually fine new blend—COUNTRY DOCTOR PIPE MIXTURE. Made by the same process as used in the manufacture of Philip Morris Cigarettes.

That was not an idle promise—

when, during the halcyon pre-war days, buyers of G-E x-ray and physical therapy apparatus were assured of maintenance and technical service throughout the life of the apparatus. ¶ To make good that promise—despite trying difficulties which the war now imposes—G.E.'s branch offices and service depots continue to function throughout the United States and Canada. ¶ Of course, it isn't possible for the local G-E service man to call as often as heretofore, what with rationed tires and gas and other transportation problems. But he is always available when there is need for service on equipment. In fact, he feels that the most important part of his job these days is to help keep G-E equipment in the best possible operating condition, for the busier-than-ever physicians' offices, clinics, and hospitals in his territory. *He will not let you down!*

Today's Best Buy – U.S. War Bonds

In your particular area this maintenance and technical service is extended through the following G-E offices and service depots:

CHILDREN ADMITTED

LIKE THE TURNIP IN THE OLD FABLE THAT REQUIRED THE WHOLE HOUSEHOLD—INCLUDING THE MOUSE—TO UPROOT IT, FEW DISCOVERIES ARE UNEARTHED BY A SINGLE PERSON.

Thus Sterile Solution Adrenal Cortex Extract (Upjohn) had its roots in the accumulated knowledge of the past; through the work of a number of contemporary investigators the possibility of such a product was demonstrated; and finally, through the combined efforts of the research and production departments of The Upjohn Company, the extract was produced in commercial quantities. Sterile Solution Adrenal Cortex Extract (Upjohn) is available in 10 cc. rubber-capped vials at your prescription pharmacy.

Perhaps some overworked doctor would like to know . . .

. . . that Biolac is a complete liquid infant formula which saves you valuable time because there are no extra ingredients to be calculated.

. . . that Biolac provides completely for all nutritional needs of young infants except vitamin C.

. . . that prescribing Biolac reduces the possibility of upsets due to errors or contamination in formula preparation since it requires only simple dilution with boiled water as you direct.

NO LACK IN BIOLAC

Borden's complete infant formula

● *Biolac is prepared from whole milk, skim milk, lactose, Vitamin B_1, concentrate of Vitamins A and D from cod liver oil, and ferric citrate. It is evaporated, homogenized, and* sterilized. *For samples and professional information, write Borden's Prescription Products Div., 350 Madison Ave., New York City.*

A Strictly Ethical Line of Quality Vitamin Products

All Ulmer Quality Vitamin Products are manufactured under the most carefully supervised and controlled laboratory conditions. Nothing has been spared in making them the very finest quality. No attempt has been made to lessen their potency to meet popular over-the-counter prices; they conform to the maximum potency permitted by the War Production Board. The result is a strictly ethical line of Vitamin Products, outstanding in quality, which meet the rigid standards of the medical profession, and are prescribed and dispensed by the medical profession.

In addition to DA-LI-KAPS, VITAMIN B-COMPLEX and HEMATINIC OVALS, the Ulmer Vitamin line includes . . .

CAPSULES:

Vitamin A
Vitamin A and D
Vitamin D
Vitamin K
Vitamin A, B, C, D and G
Vitamin A, B, D and G
Calcium Pantothenate
Wheat Germ Oil (3 M Perles)

TABLETS:

Ascorbic Acid 50 mg.
Brewers Yeast
Nicotinic Acid 50 mg.
Riboflavin 1 mg.
Thiamine Hydrochloride 1 mg.
Thiamine Hydrochloride 3 mg.
Thiamine Hydrochloride 5 mg.
Wheat Germ Oil (Liquid)

The ULMER Quality Label

Is Your Protection

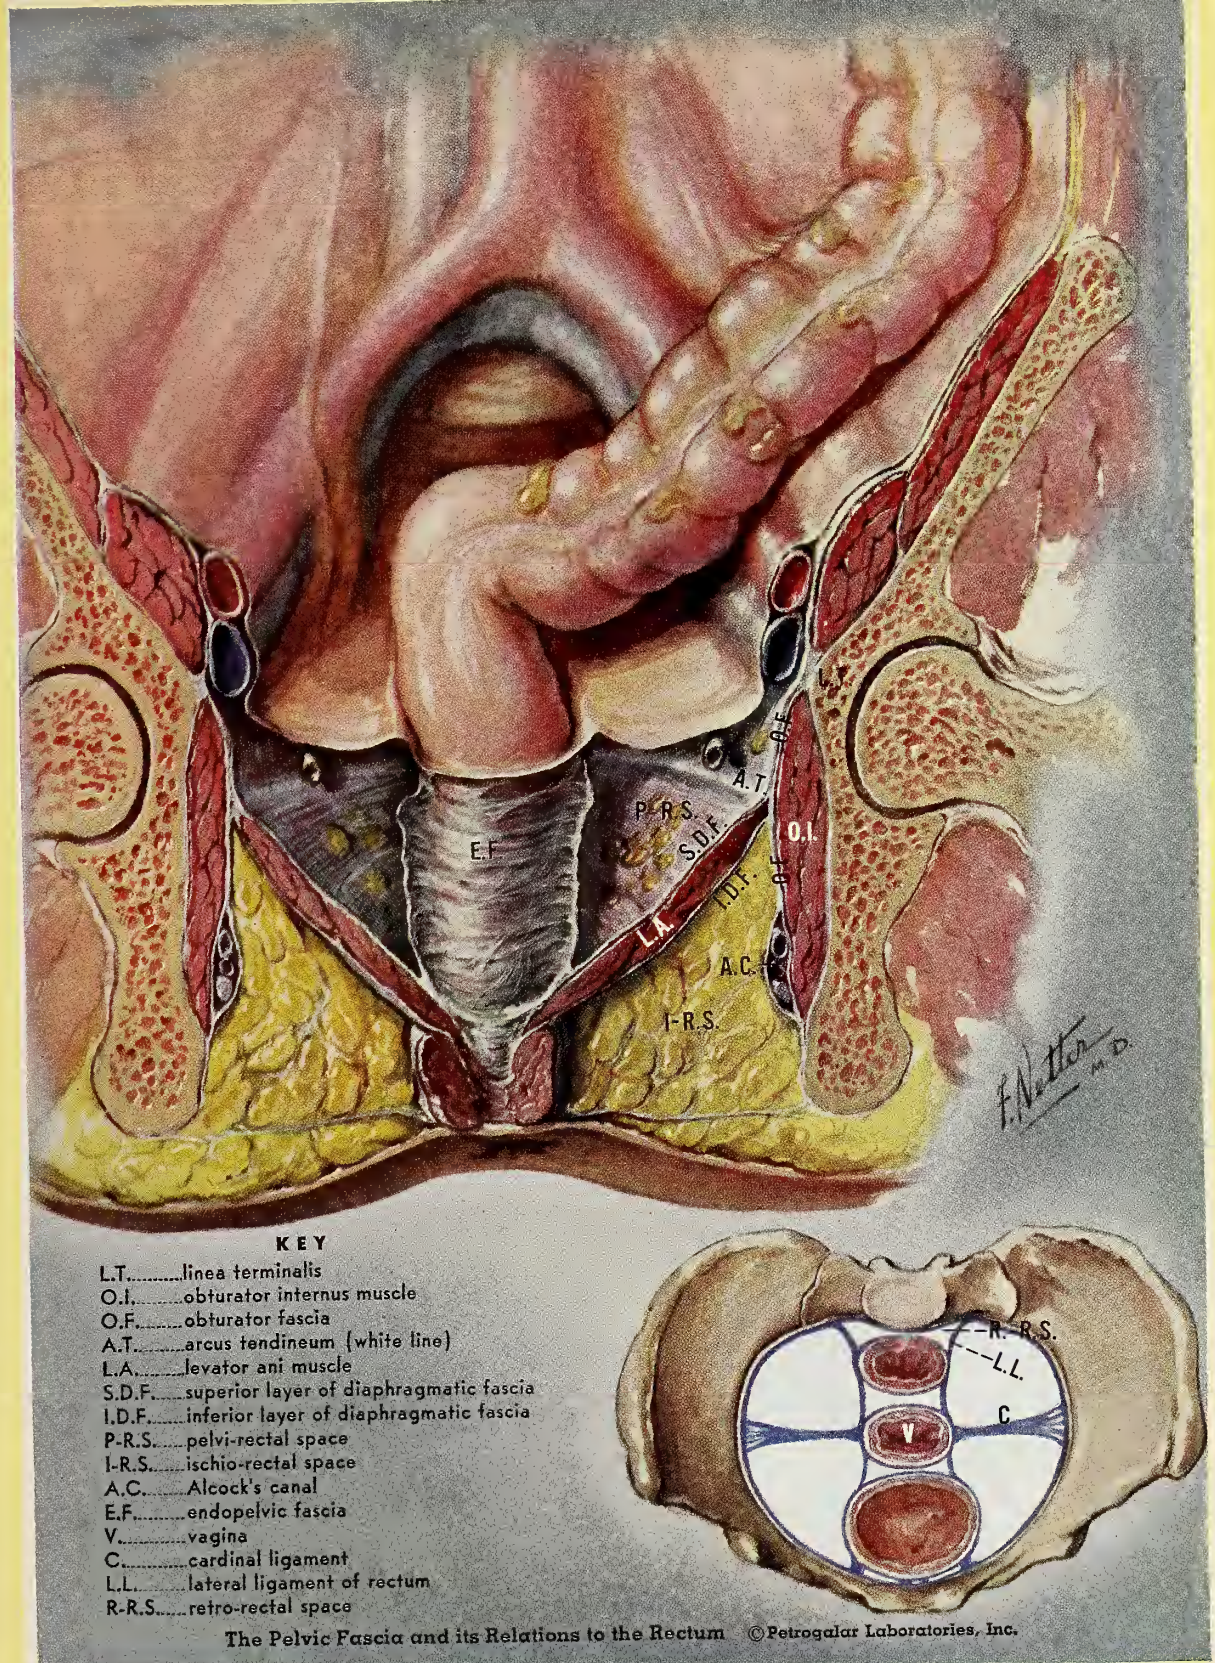
PHYSICIANS AND HOSPITALS SUPPLY CO., Inc.
MINNEAPOLIS MINNESOTA

Our compliments and sincere congratulations to the Minnesota State Medical Association, upon the Twenty-fifth Anniversary of

MINNESOTA MEDICINE



MINNESOTA MEDICINE has rendered a very valuable service to the medical profession of Minnesota. And, its recognition as one of the leading medical publications in the country, must be a source of satisfaction to every member of the Minnesota State Medical Association, as well as the editorial and business staffs.

May the next twenty-five years of your journalistic career be equally as successful and progressive!

The Pelvic Fascia and its Relations to the Rectum ©Petrogalar Laboratories, Inc.

THE *Pelvic Fascia* AND ITS RELATIONS TO THE RECTUM

The fascia of the pelvis comprises three portions: the parietal, the diaphragmatic and the endopelvic fascia.

The parietal fascia lines the sides, back, and front of the pelvic cavity. The diaphragmatic fascia covers the upper and lower surfaces of the levator ani muscle in the pelvic floor. The endopelvic fascia (E.F.) invests the rectum and the other viscera.

Thus not only do the fascial sheets of the pelvis help support the rectum, but they also form closed fossae to which rectal

may place an undue burden upon the ligamentous and muscular supports of the bowel. In addition, the hardened fecal masses may irritate the bowel wall and allow infection to take hold that may involve the interfascial spaces.

Petrogalar* softens as well as lubricates the feces. This fine aqueous suspension of oil mixes intimately with the bowel residue, assuring a soft consistency that helps restore the natural evacuation impulse.

Petrogalar is palatable and easy to take. It does not become

Petrogalar*

Helps Establish "Habit Time!"

One to two tablespoonfuls of Petrogalar daily provide bland fluid to help soften the feces and bring about an easily passed, well-formed stool. Consider the routine use of Petrogalar to establish Habit Time. It is not habit-forming.

**Reg. U. S. Pat. Off. Petrogalar is an aqueous suspension of pure mineral oil each 100 cc. of which contains 65 cc. pure mineral oil suspended in an aqueous jelly.*

Petrogalar Laboratories, Inc. • 8134 McCormick Boulevard • Chicago, Illinois

THE ARMY-NAVY PRODUCTION AWARD

FOR *Excellence*

PATRIOTISM *practically applied* has been given the coveted recognition of our government for meritorious service to the Army and Navy. Our management and employees, members of the production forces behind the men who man the guns, are naturally filled with pride and are spurred to even greater effort, *to produce in increasing volume, to maintain highest standards, to deliver on time.* We pledge continued devotion to Our Country and to the conservation of the life and health of our armed forces and civilian population.

The symbol of distinguished service will wave from our flagstaff.
We shall strive to keep it flying.

War Paint

In the midst of the blitz in England a lipstick became a symbol of democracy, bravely worn in defiance of that "wicked man's" attempt to shatter morale. Early in the history of the U. S. S. R. women protested against a ban on cosmetics, and it was lifted. These things are easy to understand when one reflects that cosmetics are an intimate part of a woman's life. They are essential to her well-being, her sense of personal fitness. When a woman knows she looks pretty she can face almost any situation with equanimity and courage. She needs her "war paint"; it bolsters her morale. During the telling months ahead our industry may be deprived of certain raw materials. Packages and containers may have to be changed. Any great emergency is a test of resourcefulness. We believe that our industry will not be found lacking in that sterling American quality. Our research facilities are directed towards finding alternative raw materials that will be at least as satisfactory as those they replace. Come what may, we'll do our best to continue to supply American women with those aids to good grooming, those props to personality, that in their modest way contribute so much to national morale.

PROGRESS IN INTERNAL MEDICINE IN MINNESOTA

E. L. TUOHY, B.A., M.D., F.A.C.P.
Duluth, Minnesota

MY assignment for this issue of MINNESOTA MEDICINE is the development of the specialty of Internal Medicine in our state. Other specialties are receiving similar treatment for the general purpose of giving a review of the quarter-century now ending in which this journal has so well served our profession. I choose to discuss the *background* of internal medicine in Minnesota. Documented reviews are regularly published in various journals, giving the year's progress not only in the field of general medicine but for such subdivisions as cardiology and gastroenterology, and we have such splendid reviews as that on arthritis* prepared by the committee studying that intricate problem. These articles and year books are available to everyone. It may orient the reader the better if I give the following reasons or purposes for this type of review:

1. The internist cannot avoid the responsibility of keeping in step with all advances in diagnosis and treatment wherever they appear.

2. I shall aim to point out, therefore, that he is well adapted to be the special integrator for coördinating group opinion and interpreting it for the benefit of the individual patient.

3. Much is said about the "science of medicine"; more of what has been accomplished in mass disease prevention (public health). But as life prolongation has obtained, the individual obtrudes as a social unit. The years are apt to bestow upon him more infirmities than blessings; he faces more and more hurdles of disease, degeneration, accidents, economic and nutritional imbalance. The list has infinite variety; each generation meets these with the physical and philosophical antidotes the period accepts from the past and currently develops.

4. For the forty years of my contact with medicine in Minnesota I say unreservedly there has been no "lag" whatever in giving our population the prompt benefit of all medical discoveries. In fact, we accept a general reputation the equal of any state in the Union. We have met our local obligations, and one of our great Minnesota institutions has given itself to the world and accepted its acclaim. Therefore, in terms of *our* people they expect little short of the miraculous.

5. Napoleon, surveying his victorious generals reporting to him their accomplishments, is said to have replied, "And what did you do the next day?" For those of us reporting about our specialties it should in some measure put us in our places. Success is another name for "capacity at re-adaptation." Let us keep that in mind.

6. For example, we should put much stress upon the medical problems that an age shift in population (geriatrics) imposes. Our massed action against epidemic and contagious diseases has been as effective as anywhere. But the hazards of degeneration, malignancy and many infectious processes remain. Most of all, the perturbed consciousness turns to science with something like the role of Lazarus at the rich man's door. We cannot bury our psychoneurotics and resurrect them to an effectiveness.

7. I wish to review the accomplishments of our guild in a period long enough after Virchow

From the Department of Medicine, The Duluth Clinic, Duluth, Minnesota.

*Hench, P. S., et al.: Rheumatism and arthritis: Review of American and English literature for 1940. Ann. Int. Med., 15: 1002-1108, (Dec.) 1941.

and Pasteur to have escaped the hardships of accommodation to their monumental discoveries, and to profit vastly by the flood of understanding that came with them. Ours has been the medical era of bacterial causation and pathological anatomical imprints. We never need to apologize for it, despite the fact that it bestowed upon medicine materialistic attitudes. I wish to sketch an outlook for physiology and its allied sciences. A great field of research and clinical application of therapy comparable to the sulfa drugs is opening up.

8. I shall name some of the men of my own time to whom our indebtedness is deep and abiding. Most of all, I wish to make recurring references to the very gifted Frank Fairchild Wesbrook, whose stirring picture* I transfer to these pages. The personal debt many of us owe him—the public debt we all owe him—has not been appropriately acknowledged. He deserves a far better Boswell than my powers provide.

Internal medicine has attained a very high standing in Minnesota. Surgery led other fields of medicine in the first two decades of this century. Gradually internal medicine has come into a dominant position.† Let me hasten to add that this has not come through unusual aggression by those in the field, but rather through a yielding on the part of surgeons to the conviction that surgery and medicine are based alike upon the fundamental sciences and upon accurate diagnoses. It is only in the decision as to whether treatment entails some operative technique, in whole or in part, or whether bloodless methods suffice. The closer and complementary association of the two basic specialties has thus come about; and this has not come to pass alone in such group clinics as at Rochester, but in all teaching, general and special hospital staffs as well. The recent exploits in California of an unlicensed but technically trained orderly found operating quite successfully (and voraciously) upon a variety of patients should convince any skeptic that technical skill alone does not produce a competent surgeon. In like manner, an internist critical of and unversed in the possibilities of operative surgery and the time and place for its exposition when indicated, is incompetent in this specialty no matter how erudite he may be or accurate in his diagnoses. These principles apply to all the specialties, as I shall later comment upon. Most good general practitioners of medicine are really internists, and the reverse holds equally. They should be the first to pass upon most chronic disabilities of adults and many acute disorders as well. This job of being a clearing house for other specialties may, however, be neither profitable nor comforting where the public too avidly adopts specialism and the specialist is so lacking in inhibitory faculties that it may not be easy to distinguish him from the California orderly. So much for definitions and delineations.

Regimentation and Medical Assignment

We are occasionally reminded of the chagrin of some of our brethren in the armed forces who are delegated to nonmedical or "book work" duties. In the face of military emergencies this seems inevitable; but in the broader sense it is only one aspect of the general regimentation that comes to all business and vocations where a "planned economy" supervenes, regardless of its type or source. Laymen (social workers or otherwise) are not intrinsically despicable simply because they would wish to see all our medical work organized in mass moves at eradication of any material or emotional (soma or psyche) obstacle that obtrudes in their devisement of an economic Utopia. In fact, such mass action under our own guidance has gone a long way in the eradication of communicable disease (diphtheria, smallpox, typhoid, malaria). Institutionalizing the tuberculous has greatly limited that scourge; it has done little, however, to check mental disease; and veterans' hospitals are for the most part doing no better with the high percentage of their anxiety-oppressed patrons. Not a few of these use their afflictions as a shield against adversity and the hospitals as a dietetically ideal parking lot.*

The internist cannot afford to conclude that any complainer's afflictions are "functional" until he has proven by painstaking routine that objective disease may not be a factor, but various estimates agree that where this care is taken at least 75 per cent of our patients are functionally disordered and mass attempts at their cure offer

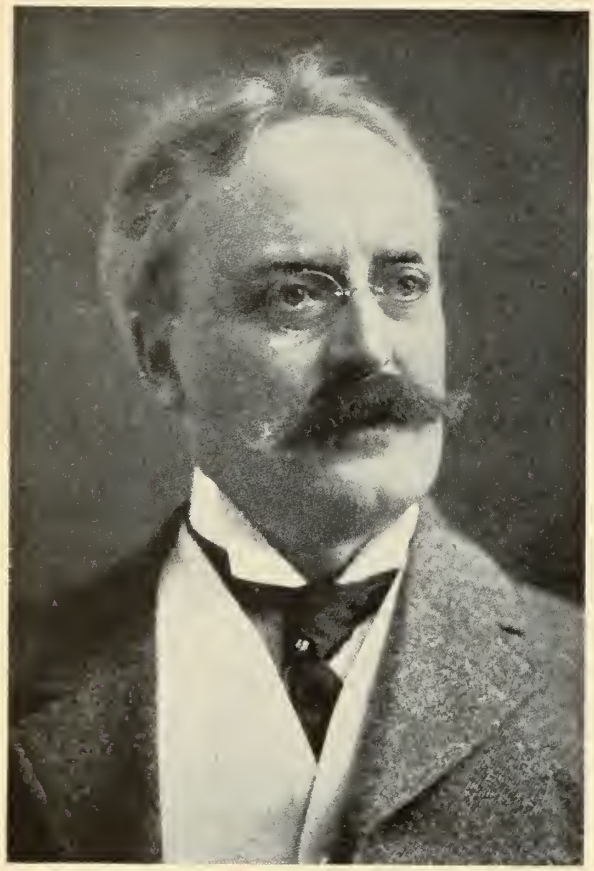
*This photograph is taken from "Forty Years of the University of Minnesota." It was edited by the late W. W. Folwell, and published by the General Alumni Association in 1910.

†Staff Meeting Bulletin, Hospitals of the University of Minnesota, p. 393, June 5. 1942.

*This must not be construed as any criticism of the medical staffs of these hospitals. Where medical service is contingent upon any other factor than the individual physician's decision then those with subjective distress abuse the privilege and burden the system.

ittle. The records of most charitable dispensaries ield the proof of that statement. For one item, here is so little of the opportunity at *integration* n the part of some well-poised guide whose urpose it is to assemble the findings of all tests nd specialists in the manner so well outlined y Professor Barker of Johns Hopkins. I introluce this statement for two reasons: (1) because t touches to the core the matter of the abuses f excessive specialism; and (2) because the inernist is by necessity as well as training the best ntegrator. I propose to discuss the route by which most men of this period have attained the specialty of internal medicine. Some of the younger men entering the profession may be interested. It gives me an opportunity to introduce to them certain personalities to whom they are deeply indebted, albeit in the current of their hasty and turbulent training there is little opportunity to give them much of an immediate not to say remote historical background. Specialties in medicine are with us to stay. Those entering into the specialties must not delay their preparation too long. The more cloistered and limited the field, the less need there may be for a broad foundation. A. J. Carlson's comment is, as always, very thought-provoking: "The conscientious practise of modern medicine is becoming so complicated and costly as to almost *exceed the intellectual capacity of the ablest men.* Again I see no cure for this. Who shall bear the necessarily increased cost of modern medical service, the individual or society? I do not know the wisest way." No, indeed. They say we are fighting two wars: a horizontal global war, which we shall win; and a vertical class and racial war, the end of which awaits a millennium. Society is not likely to accept our past record (notable as it is) in yielding to us a continuance of our rugged individualism. In the matter of life prolongation, elimination of preventable disease, promotion of individual comfort and efficiency, we have established indeed a challenging record. Science has found in its linkage with medicine one of its greatest agencies for man's beneficence. When we speak of freedom we must never forget that the freedom of the will has been guaranteed by a higher authority than any court or ruler. Men go neither to heaven nor to hell in mass groups. Kipling put it: "The sins they do by two and two, they must pay for one by one." No specialty within medicine, with the single exception of neuropsychiatry, demands such a broad understanding of the human consciousness as does internal medicine. Routine procedures, impersonal approaches, are consonant with problems of epidemic or military necessity. Surgery began with the treatment of war emergencies (Ambroise Paré). War has always advanced the surgical field; internal medicine thrives on periods of peace. There is the need of reflection—philosophical periods of retreat (Osler). The "natural born internist" does not exist. He comes into his greatest usefulness when he scans the current medical literature with unflagging zeal, when he sharpens his own powers of observation thereby, and when he has had enough contact with the classics* so that he finds peace and relaxation in rereading his own favorites. If he qualifies under these headings we may well permit him to venture the thrombosis of his own coronaries through misguided physical exertion for which he is untrained but which yields him rare delight.

Great Medical Personalities In Minnesota



I choose to go back only to the period of my own tutelage, where my own contacts furnish the material. I trust this comment† may secure for me some indulgence and rescue me from the opprobrium of autobiographical verbosity.

Charles P. Sigerfoos had a profound influence upon those of us who took our academic training at Minnesota. He taught biology, and led classes in zoology, physiology and embryology. Since the microscope became such an important instrument for research in medicine and establishing better clinical diagnosis, this great teacher deserves particular mention, although he never had any direct contacts with the Minnesota medical faculty. I think I am right in stating that Hal Downey secured his urge and began the development of his interests within Sigerfoos' department; and everyone knows of his great contributions in the field of hematology, begun when he was a relatively young man. Scores of others, like myself, at least were introduced to a world of interest opened up by the microscope; we were made ready for the grounding in microscopical pathology that was later available. Twenty years slipped by, however, before the con-

*Under the term "classics" should be catalogued many resources other than books or essays. Many pay lip service to Cervantes, Bacon, Shakespeare and Montaigne; but never read them. The American Physicians Art Association held an exhibit at the A.M.A. meeting in Atlantic City in June, 1942. There are several doctors' orchestras and a great many nonplayers are arch collectors of symphonic records.

†And save me from censure for leaving out the names of so many equally deserving.

sciousness dawned upon me of the influence that that charming, punctilious and precise educator, Professor Sigerfoos, had upon me. Many others have expressed to me the same feeling of sincere devotion to that rare teacher.

Frank Fairchild Wesbrook

The question is often posed by anxious parents: "What is the best choice of subjects for those hoping to matriculate in medicine?" The inquiry is not easily answered. Studies such as I have mentioned above certainly molded and prepared me. Perhaps, however, in my philosophical moments I am replaying some of the memory records grooved by contact with the beloved and gracious Maria Sanford; or I am disking from a matinee with that vivid genius of psychology, Harlow Gale; or a rollicking chant with the gifted "Dickie" Burton—he never to be forgotten—his Shakespearian course gone to mold along with the dim recollections of Henry Irving and Walker Whiteside. After 1914 and 1929, despite attempts at playing the old records, I was able to reproduce only an occasional strain of Anderson's facile historical cataloguing of the countries in continental Europe; and some figures by economist McVeigh—methodical social and political balances; but need I add that much has happened to European schedules and the world's economic stability since the above fateful years were ushered in?

Frank Fairchild Wesbrook

I consider that Wesbrook was responsible, more than any other man, living or dead, for medical undergraduate teaching in Minnesota. He was the most attractive personality I have ever met. I admit at once that in so far as he is concerned I am guilty of hero worship. In many ways I have no right to claim him for the specialty of internal medicine, because he obviously was primarily a bacteriologist and pathologist; nevertheless, as I scan the period of approximately a quarter-century since his death in 1918, I conscientiously feel that the ideals and schedules of teaching, the correlation of all forces for the control and the alleviation of disease were all a part of his superb consciousness. Long before others grasped the idea of one medical school within our state, attached to our university not as an appendage but as a living, active, dynamic force therein, he blueprinted the prospective development of our medical school—an accomplishment we now so proudly survey. Too little has been said about this great man and this lovable character. This was brought home to me forcefully a few years ago when a teacher here for a short period asked me on occasion something like this: "Who was this man Wesbrook about whom so much is said and who seems to have left so little in the way of research?" I felt no resentment at this remark; I hope I did not show it. But a great nostalgia came over me, out of the feeling that after all this inquirer, bent chiefly toward research problems and output, was right. No one ever desired more eagerly and wistfully to devote his life to research than did this glorious individual who, in 1906, became the dean of the College of Medicine and Surgery at Minnesota, and held that post until January, 1913, when he was made president of British Columbia University. For the sake of the records I beg leave to give you a short résumé of Wesbrook's life.*

*I have secured the details pertaining to Wesbrook's earlier years from his brother Donald. Donald and Beth Wesbrook are now living in East Barnard, Vt. When the Wesbrooks came to Minneapolis the much younger brother Donald lived with them. He ultimately graduated in engineering at Minnesota. He married Beth Barney, daughter of a well-known family in southeast Minneapolis.

Canadian born, July 12, 1868, he had coursed through his preliminary training (London, Ontario, and Winnipeg, Manitoba) and had attained a B.A. degree when he was only nineteen. Three years later he had an M.A., an M.D. and C.M. from Manitoba University. He had had an internship and a short period as a railroad surgeon at Banff, Alberta, and found himself a year later taking the famous maternity course at the Rotunda Hospital in Dublin. Perhaps this item explains why, when I first met him, fellow faculty members called him "Paddy." Something else came up, however, and the next three years found him doing research in pathology at Caius College, Cambridge. He had secured and won the John Lucas Walker fellowship. He spent three years thereafter gaining further experience in the King's College and St. Bartholomew's hospitals in London, and spent considerable time in Germany, particularly at Marburg. In this period he had many continental contacts, to which he often referred. He met the great researchers of that post-Virchow and Michael Foster period; he brought back with him to Canada in 1896 that Promethean medical fire that so many others like him have spread around the world and so continue to do. His own university (Manitoba) gave him the call for the professorship in pathology. He did not remain very long in Winnipeg because he was called soon thereafter to become professor of pathology and bacteriology and public health at Minnesota. He had, however, taken time to marry the daughter of Sir Thomas and Lady Taylor. Sir Thomas was chief justice of the supreme court of Manitoba.

This is just a recital of who he was and where he had been, but that succession of dates and appointments does not reveal the man. Anyone observing him swinging across the campus would not need to be told that he had won medals at home and in England for proficiency in running, jumping, pole vaulting, bicycle riding, shotputting, as well as both single and shell crew rowing. When I knew him best he was a member of the Athletic Board of Control. He was the most gracious of hosts and the most charming of companions; but let no student ever presume upon such acquaintance as these opportunities might bestow as an occasion for any letdown of the standard he set within his departmental teaching. He would swing into the lecture room with an agility reminiscent of his pole vaulting; for a few moments he would vault into his prepared lecture, but like many geniuses he was apt to wander off on other sidelines, promoting considerable confusion in the student's notes. If one was able to catch some of these sidelines and his enthusiasm that was enough. Some of the best lecturers, after all, are the poorest teachers. Well, wherever Wesbrook joined any group he soon became the center of animated conversation. His clothes always fitted him well but were never ostentatious; he kept himself well groomed. He was a connoisseur of meerschaum pipes. He allowed his friends (and others) to take up a great deal of his time. He was a gentleman to the core, and he acted the part even toward those whom he did not like. As a result of all this and of his official position he was placed upon endless committees and faculty appointments. No assignment of this type ever became so onerous (and so productive of good) as his directorship of the laboratories of the Minnesota State Board of Health. The late H. M. Bracken, Secretary of the Board, lived but a few doors away from him (near Tenth Avenue Southeast, Minneapolis). It was Wesbrook and Bracken who sent me to Duluth in the summer of 1905 to open the branch laboratory for the State Board of Health at St. Mary's Hospital. I was soon to learn why Frank Wesbrook was never to be granted any time to do that research for which he was so superbly fitted when he came back from Europe to Canada when he was only twenty-nine years old. The research opportunity which he so much craved has since fallen into the most competent hands of such workers as Cecil Watson and Wesley Spink. He would be immensely proud of them, even as we all are. But, Minnesota was pioneering medically. Great general surgeons were developing at Rochester; Minnesota had great clinical teachers, but aside from those like Louis Nippert and Arnold Schwyzer (European trained) they were mostly trained in the Osler tradition, and lacked his contact with the clinical laboratory and the postmortem table. Minnesota might also have boasted of rollicking adventures with smallpox, a typhoid rate that competed for ascendancy with any in America, and aside from a lone protesting voice, such as that of Longstreet Taylor of Saint Paul, tuberculosis, with its terrifying incidence among young adolescents, was accepted everywhere,

even as the Indians had accepted it after the white man came.

H. M. Bracken was indefatigable. In his official position as secretary of the State Board of Health he kept Wesbrook in a stew a large part of the time bolstering up his blitzkrieging officialdom. And yet, let me add at once, Bracken was usually right. He had had some experience before the mast. He absorbed no profanity from this service, but others took the incentive thereto from him. Wesbrook, the diplomat, spent precious hours and days mollifying people to whom Secretary Bracken had sent blistering letters, presently reminiscent of a cabinet member in Washington who, among a thousand other aggrandized duties, is custodian for the Indians. Like the present cabinet member in Washington, Bracken† was noted for his bluntness more than for his obvious knowledge of the possibilities of public health.

Frank Wesbrook left medicine to accept the presidency of a university (still largely in prospect) when he was only forty-five years old. He died of hypertensive cardiovascular disease at fifty. I have had much to do with treating hypertensives. For three years now statistics which I have accumulated show that of all the patients we have seen at the Duluth Clinic since 1915, and where we were able to trace the deaths, just about 50 per cent died of cardiovascular renal disease, with or without cerebral complications. The average age, however, is about sixty years, and a recent medical writer has stated that at forty-five a doctor is at the height of his value to the community and his profession. At least ten years of Frank Wesbrook's life were ground out and destroyed through useless controversy and nonproductive administrative duties that never should have been his. His standing as a scientist is abundantly attested to by the fact that he belonged to the Association of American Physicians, the Association of American Pathologists and Bacteriologists, the London Pathological Society, the Pathological Society of Great Britain and Ireland, the Society of American Bacteriologists, and the American Physiological Society. In 1905 he was elected president of the American Public Health Association. He was honored by the United States Government in making him a member of the advisory board of the hygienic laboratory for the United States Public Health and Marine Hospital Service. Who, I ask you, among our present researchers, is going to equal that record? When it came to the matter of adjudging the University of Minnesota medical school for certification as a Class A school it was Wesbrook who convinced Abraham Flexner of the Rockefeller Foundation that Minnesota had a school with a Class A destiny.

The influence of this great character and personality became apparent early. The intervening years have only attested Wesbrook's great capacity to stimulate others.

Louis B. Wilson, a Saint Paul high school science teacher and a genius in his own right, became Wesbrook's "first-born" in his scientific family. Years after Wilson was absorbed into the great clinic at Rochester, Wesbrook would almost tearfully refer to him as parents now speak of their sons called to war—a great and needed service and a glorious opportunity. To a recent generation who know Wilson chiefly as the genial ogre dispensing the benefactions of the Mayo Foundation, it should be told that a great surgical center was blueprinted by him, to develop into the great scientific, teaching and medical diagnostic center now universally acclaimed. Other men followed in rapid succession—men who have made medical history in Minnesota. Some, like Bob Mullen and Tommy Martin* (my associate), did not long survive Wesbrook—but they had acquired the touch of genius. Harold Robertson came and followed Louis Wilson to Rochester, where he turned the cold and rigid light of necropsy analysis upon the handiwork of the oldest to the most recent recruits in service. Medical history was indeed unfolding. To what beginnings we had made in Duluth, Robertson sent to us George Berdez, and our clinico-pathological conferences at St. Mary's Hospital have carried on uninterruptedly for twenty-two years. Conferences to include roentgenologists and physiologists promise for the future the best method of integrating the activities of all specialists with the main medical

†One of his major legacies to Minnesota was the Piersons. In the field of administration and vital statistics in the secretary's office at the capitol in Saint Paul, they have been invaluable.

*I have made no mention of x-ray in this review. Too much credit cannot be given to roentgenology in this period. I procured the first workable fluoroscopic unit used in Minnesota. Returning from Vienna in late 1912, after seeing the work of Holzknecht and Kreisfuchs, no one could provide me with any similar apparatus. Hearing that Case at Battle Creek, Michigan, had a handmade working unit I visited him. A Chicago firm made a machine for me following Case's instructions. I never became proficient with it, but Martin did. Gastro-intestinal fluoroscopy (so diagnostically essential) is one of the most exacting techniques. Relatively few men are capable of becoming experts in the field. The late R. D. Carman was soon to demonstrate its possibilities at the Mayo Clinic.

current of the period. Men who did not remain long in Wesbrook's laboratories or came in later, as for example, Marx White, the late Arthur Hamilton, Moses Barron, and many others, have been among our best clinicians and teachers.

It is trite to restate that our guild has made more advance in the healing art since the turn of the century than in all preceding time. These accomplishments have multiplied responsibilities and complexities far beyond the permanent prestige they have bestowed. We happen to be living in the most violent social and economic era of all time. All specialists are too prone to attribute our present life extension to their efforts given to the individual sick. We are prone to pass over to bureaus and bureaucrats the management and sustenance of public health activities. Minnesota has been favored beyond the average state in this regard because political maneuvering has not cut into our administrative health activities. We are indebted for this in no small degree to the well-laid plans of both Wesbrook and Bracken and to the distinguished men and women whom they directed into public health work. First credit in this connection must be given to Dr. Orianna McDaniel who, for many years, worked very closely in the laboratories of the State Board of Health with Dr. Wesbrook, and who became his successor. Dr. Albert Chesley grew up, medically speaking, with the department. He worked with the laboratory while a medical student. Later he profited greatly from the pioneering in epidemiology in Minnesota by H. W. Hill.* Chesley thus secured a grasp of administrative health problems that comes to but few in any generation. Fortunately, he had the physique and personality enabling him to acquire the dynamic urge of Bracken, the ingratiating poise of Wesbrook, and the statistical trend (mathematics) of H. W. Hill. Our profession is deeply indebted to him, particularly in these times of political usurpation, when our professional birthright could be so easily exchanged for political pottage. We face the superinvolved issues of the global peace that some time will follow the global war; we need a continuance of the most alert public health programs, because with modern transport methods the spread of diseases and their vectors is only exceeded by the rapidity of the spread of ideologies.

In order that the specialists of the future may profitably service self-sufficient patients, the latter must not die in youth or be maimed later by epidemic encephalitis, poliomyelitis, malaria, or rickettsial infections. Undernourished, impoverished, downtrodden populations are unable to accept and carry out, let alone support, standards of individual medical care to which we have attained. It behooves us, therefore, to recall our indebtedness to the field of public health, and again I must refer to Wesbrook's contacts with it. He was of the generation that produced Adami, Theobald Smith, William H. Welch (Baltimore), Park (New York), and Livingstone Farrand (later President of Cornell University). He was intimate with all of them. They had in common the zeal to spread through the Americas the lifesaving precepts that those after Koch, Loeffler, Pasteur and Von Behring were developing. Wesbrook often spoke of his contact with Klebs and Metchnikoff. After war service in France in 1918, Albert Chesley was sent by the Red Cross into Poland, where typhus and other epidemics were assuming threatening proportions. We may know from this background that it is no accident that our state health administration is qualified to meet any world emergency. It is time to ask ourselves, Are we individually as well qualified? I ask this question with no intention of fashioning an answer. I wish to comment upon the Minnesota medical field as I see it; and especially upon the educational facilities and agencies through which we may hope to retain standards of usefulness entitling us to evade demeaning regimentation.

Maintaining Standards of Medical Education

E. T. Bell, professor of pathology at Minnesota since 1920, and with the department since 1911, has followed in the Wesbrook tradition with a fidelity of purpose and research ability (kidney pathology) that is everywhere admired and acknowledged. He and his staff have packed into their teaching schedules no summation of canned textbook extractions, but vivid daily observations of all that is seen in the ward, developed

*H. W. Hill was Canadian-trained. He remained in Minnesota up to 1912, when he returned to London, Ontario. He returned, however, to Minnesota, a number of times, and once directed the Minnesota Public Health Association. He is living in Minnesota now, but in retirement. He deserves a very high place in recounting our public health accomplishments. In 1906 I accompanied him and saw him in action when we studied typhoid epidemics in Hibbing, Cloquet, and other northern cities. There certainly was much to do to develop proper water supplies and sewage disposal. Neither typhoid vaccination nor water chlorination had yet been developed. Frederic Bass and H. A. Whittaker were still to give us their great services from the mechanical and chemical engineering side. I recall that Hill kept repeating, "Why, we have had more typhoid this year, either in Cloquet or Hibbing, than has the whole state of Massachusetts!" That was the challenge that he met.

at the operating theatres, and found at necropsy. We shall continue to have the right kind of doctors if they have his type of basic training. The student entering his classes in his final two years encounters no new vocabulary or confusing technique. Clinical concepts are naturally implemented into the basic pathological instruction. When the student becomes an intern, and later in any type of staff organization, he is able to hold continued contacts and counsel with the clinical and tissue pathologists. I mention this obvious situation (now obtaining in all Class A medical schools) not only to give credit where it is due but to point out that this fortunate sequence does not obtain in the field of physiology and its allied sciences.

Medical Journals and Publications

The world-wide exchange of medical ideas arises from our splendid and varied current literature. Keeping up with it even in a limited field has left so appalling a task that it must be made to yield satisfactory recompense. Endless and fatiguing reading is not the answer. Some men have an uncanny capacity for collecting from the medical literature the very items they are able to use in their current practice and apply in cataloguing their daily erperiences. Let me illustrate in terms of some of my Duluth associates. In 1927 Lloyd Merriman* was called to the western part of the state to see the mother of a dentist confrere. She had a curious typhoid-like illness that had been very puzzling. By recalling a short note that he had seen in the *Journal of the American Medical Association* he was led to make inquiry concerning the skinning of some rabbits which had preceded her illness. He was able to prove, through specimens sent to the U. S. Public Health laboratories in Washington, that the disease was tularemia. He has been given, therefore, great credit for this "first" in Minnesota. Within a few weeks a fox farm operator on the North Shore came into St. Mary's Hospital; he lived only a few days. An intern, imbued with the remark he had heard about Dr. Merriman's experience, awoke to the situation of the man's scarred finger and axillary adenitis just in time to send a blood specimen to the late Dr. Edward A. Francis. An autopsy was steadfastly refused until the term "rabbit disease" was suggested, and then everyone, including the undertaker, was most zealous for an examination. Drs. Richard Bardon and George Berdez† were able to report and send a specimen to Dr. Francis of this first autopsied human case of tularemia with a caseating pneumonic process in the United States.

As a result of his wide reading and extraordinary memory, Dr. Frank J. Hirschboeck has an imposing series of "firsts." His was the first report received for publication in the United States on massive atelectasis of the lungs. A man developed bilateral atelectasis after an abdominal operation. These are Hirschboeck's own words: "I remembered having read an article by Tingley and Elliott in the London *Lancet,* published in 1911, in which they reported eleven cases of massive atelectasis following surgery . . ." Scrimger of Montreal, Canada, had reported the condition in February, 1922. Hirschboeck's* report came out in early August, 1922. Hirschboeck made the first report in Minnesota to the State Board of Health on a case of lethargic encephalitis occurring at Carson Lake, Minnesota. In making this report he referred Dr. Green, epidemiologist for the State Board of Health, to an editorial he had read explaining the disease. He made this report in March, 1919. He correctly diagnosed another case one month later, after listening to the symptoms as related by the late Dr. A. J. Braden. It requires an agile memory to bring to mind something you have read six years previously. Schultze, in Germany, reported an instance of agranulocytosis in 1922. Hirschboeck recalled this and correctly applied the diagnosis to a patient of Dr. W. G. Strobel, whose death occurred on February 4, 1928. Hirschboeck later reported this case to the Minnesota Society of Internal Medicine, but he did not publish it. He has others which appear equally uncanny, but I recite these evidences less to remark the genius that he is than to point to a masterful way of utilizing medical texts and articles. Next to the credit that comes from first describing a disease or syndrome should come that for recognizing it from the description and interpreting it to one's fellows. MINNESOTA MEDICINE has been the outlet for much of that type of reporting. It performs for our district as does the *New England Medical Journal* for the region medical-

ly tributary to Boston. This type of journal as well as the so-called "pure research" journal, each has its place. The results of "pure research" often attain applicable clinical interpretation only after it has been transposed by working clinicians into the papers that make up the programs of our numerous medical societies.

Special Medical Societies

Complaints have come on occasion from our county, state and American Medical Association administrative officers that a surfeit of special societies has withdrawn program support from them. The implication is that those offering original material prefer to give it to societies of specialists and to specialist journals. There is no need for alarm. It works the other way. Men certified for special societies attain to that position by their efforts at limitation of their field and perfecting themselves within it. Certification by boards is only a formal way of standardizing and adjudging candidates and the reports made of their work. The regret is that general program builders find it difficult to induce general practitioners to pledge themselves to give papers; and it is true that "headliners" are sought out to attract attendance at meetings. The result is that all therapeutic advances soon get to the general practitioner and he uses them well to the extent of his diagnostic ability.

Leonard Rowntree while in Minnesota was one of the prime movers for starting and developing the Minnesota Society of Internal Medicine. The membership of sixty has provided a place for representative internists from the Twin Cities, Rochester and Duluth. The aim is to include more men from the smaller cities as they are certified. The Mayo Clinic and the University faculty members have given great impetus to this society. I hold it (with its two meetings yearly) to be the most helpful and stimulating of the many to which I belong. The meetings are open to invited guests from adjacent states. The consolidated programs, with ten-minute papers and five minutes more for discussions, rivet the audience's attention and develop lucid expression. All praise to the specialist societies. Next to the current literature they inhibit "lag" in the "March of Medicine."

The American Colleges and Graduate Education

The College of Physicians had one of the best of its annual sessions in Saint Paul in May, 1942. Bringing the meeting to Minnesota (a signal honor) was largely the accomplishment of Dr. John Lepak of Saint Paul. The college plans to meet the demand for some method for special training of internists seeking either certification or refresher courses. Cecil Watson at the university and Edgar Allen at Rochester planned two-weeks courses to groups of sixty men each just prior to the Saint Paul session. The courses were most enthusiastically received and praised. Such graduate courses have been given preceding the annual college convocations for five years. The war is likely to interrupt them, but regional meetings should be planned not only for the men at home but those in the armed forces as well.

This educational program is the most profitable goal of the American College of Physicians. There are all too few places available for graduate fellowships in medicine. Minnesota is preeminent because of the Mayo Foundation and our university. The future must develop more such facilities; and with the multiplication of government and military hospitals some coördinated plans should be easily worked out. Hospitals designed for various military exigencies (orthopedic, psychopathic, facial and dental reconstruction) are already on the way. It is time to deviate widely from the basic ideas of physical reconstruction and attack the more common and complex problems of functional imbalance.

Physiology, Pharmacology, Anesthesiology

These fundamental sciences provide the same avenue of approach to homeostatic imbalance that pathology and bacteriology have given us for so-called "organic disease." Whether in peace or wartime we need more neuropsychiatrists and fewer surgeons is a question. I have traced how internal medicine has profited superbly by additions to the field of men trained in bacteriology and pathology. More men should come into the field similarly trained in physiology and its allied sciences. Carlson, Cannon, Ivy and Wiggers have been showing the way for two decades. Mann and his coworkers at Rochester have given the impetus to scores of the Mayo clinicians (all branches): liver disease (Snell and Butt); vascular disease (Brown, Allen, Willius, Horton)—

all leading toward physiological and pharmacological exploitation. One of the meatiest books ever written on the heart was by the late Arthur Hirschfelder* of our department of pharmacology. Yet after he came to Minnesota from Johns Hopkins he lost all contact with clinical teaching. I am not imputing blame or criticism. I am simply stating a fact: few interns from any medical school in the past twenty-five years have ever admitted (to my pointed question) that the intellectual inoculations they got in the sciences, allied to and including physiology, ever worked longer than to confer temporary immunity to the blight of the final examinations. This is outrageously wrong. A few men have seen the light. Henry Ulrich received a permanent inoculation at Johns Hopkins. Among his many contributions has been his molding of the Minnesota Heart Society, and insistence upon the cultivation of physiological understanding. Hilding Berglund,† when professor of medicine, brought the greatest gathering of distinguished medical scientists ever to assemble in Minnesota. It was for the purpose of an organized symposium on kidney disease. Recall the distinguished names from home and abroad: Richards from Pennsylvania, Volhard from Frankfort-on-Main, Isidore Snapper from Amsterdam, and many others. Physiology and pharmacology were co-equal with pathology in the review of research and clinical application. George Fahr, with his students, has brought the spirit of clinical physiological approach to his routine and research at the Minneapolis General Hospital. John Lundy has made history in a greatly expanded field of anesthesiology at the Mayo Clinic. What he is doing largely for surgical patients must be expanded to cover many technical phases of pain relief in general and the methods to keep the body constants stabilized.

The Center for Continuation Study

Medical schools do little more than plant the seed that replenishes the guild personnel. Thereafter there remains much to be done in the period of cultivation. Not all fields and soils are alike. Different purposes and products are best served by judicious individual selections. It is so with doctors. It will be a sad day when regimentation makes doctors all alike, even as post-office clerks.

The continuation service center at the university meets the needs of our calling in a manner made very obvious by the extent to which its exquisite accommodations have been used for medical sessions. It is not easy for some of us to clearly dissociate the building from our medical mentor, William A. O'Brien. His tact and enthusiasm have been invaluable. His radio work on behalf of the public is a popular presentation, enlightening, informative, and just enough of medical appeal so that it misses evangelistic exhortation. He knows doctors as do few men—their needs, idiosyncrasies, "pet peeves," and what they like. This has given him much insight into medical staff and program organization. The Staff Meeting Bulletins, under the technical assembling of Gertrude Gunn, reflect all this. It was in the "Gossip Column" in one of the 1942 issues that I first learned that the specialty of internal medicine was in first place in Minnesota. It was further noted that medical visitors to the University Hospitals commented upon this and congratulated Professor Wangensteen upon his development of physiological principles in surgery.

Let us aim to make physiology, pharmacology and anesthesiology a working division right in the midst of our clinic problems. It is incumbent upon us to have modern anesthetists in our hospitals without delay. Perhaps in war service some preliminary training may be given to men qualified for this service. But over and beyond any immediate emergency utilization, as for shock, burns, blood bank service, et cetera, looms the much bigger problem of the psychoneurotics and the insane. The next quarter-century should plan to do something for them through studies of their physiological imbalance. It does not seem especially hopeful simply to house the insane. Functionally disordered folk (anxiety neuroses) are found for the most part among our most civilized people. Let us study civilization.

---

*In London in 1912 Sir Thomas Lewis asked me about Hirschfelder's clinical services and remarked that they must have been extensive because of his book. Hirschfelder, Arthur Douglas: Diseases of the Heart and Aorta. J. B. Lippincott Co. Three editions, 1910, 1913, 1918, respectively.

†These lectures were later edited and arranged by Berglund, Medes, Huber, Longcope and Richards. Lea & Febiger, 1935.

Addenda.—The *Journal of the American Medical Association* (Dec. 5, 1942) saw fit to RADIO from Moscow Lepukaln's report upon the War Surgery in Russia of "Academician Burdenko." The reader will note at once the *physiological* basis of the Russian research and how fully it guides their newer surgery.

CORONARY DISEASE

Certain Significant Contributions Made During the Last Quarter Century

FREDRICK A. WILLIUS, M.D.
Rochester, Minnesota

IT IS fitting that this commemorative issue of MINNESOTA MEDICINE, marking the completion of twenty-five years of constructive editorial effort, should contain certain reflections on the medical progress made during its existence. While the medical sciences have made almost unbelievable progress, civilization as a whole has been regressive, as indicated by the fact that at the time of the issues of Volume 1, Number 1 of MINNESOTA MEDICINE most of the world was at war and again, with the appearance of Volume 26, Number 1, virtually all the nations of the world are gripped in mortal conflict. It is lamentable that the advances in medicine, designed to prevent and control disease, to ameliorate suffering and to prolong life, could be devastated by the ruthless slaughter of countless human beings by demonic forces of destruction. This paradox is a challenge and demands the greatest effort of the medical profession, now and after victory comes, to make a repetition of this catastrophe impossible.

The advances in cardiology have been so great and numerous during the last quarter century that it seems desirable to limit this review to a single phase of the subject. So outstanding have been the contributions dealing with coronary disease that an entirely new philosophy has been evolved, not only concerning itself with the coronary circulation, but integrating itself inseparably into the entire subject of cardiovascular diseases. Even in this one phase of cardiology it is impossible to acknowledge the efforts and contributions of all the workers who have made progress a reality.

Anatomy of the Coronary Circulation

In 1918, F. M. Smith,[60] studied the coronary arteries of man and the dog by injection methods and roentgenologic depiction of the circulation. His studies indicated a close similarity in distribution of the main vessels in both man and the dog and he concluded that on this basis the dog's heart was suitable for experimental purposes. He also demonstrated small anastomotic branches between the arteries of the right and left ventricles.

Three years later (1921), Gross published his important monograph dealing with the blood supply to the heart. This very comprehensive work comprised a study of many specimens of the human heart, both normal and pathologic. Injection of opaque media and subsequent roentgenography afforded remarkable opportunity for comparative observations. Unusually small vessels were clearly visualized and anastomotic vessels were readily demonstrated. The distribution and ramifications of the arterial tree were studied and the distribution of the circulation in the various periods of life was compared. Gross concluded that a relative regression of the arteries of the right side of the heart occurred as age advanced. This contention, however, has been disproved by subsequent studies. Gross' work was outstanding and opened the way for subsequent studies, all of which have been contributory to a clearer understanding of the coronary circulation.

In 1924, Oberhelman and LeCount called attention to a most important observation regarding the coronary arteries. They emphasized the great variations which occur in the distribution and ramification of the vessels in individual cases. Their observations have been repeatedly verified by subsequent investigations.

Wearn,[65,66] four years later, called attention to the extensiveness of the capillary circulation of the heart and discussed the role of thebesian circulation under normal and diseased conditions.

Whitten's studies[71-73] (1928, 1930) of the coronary arteries were outstanding. Using the injection-corrosion method with a differential color scheme for the arteries of the right and the left sides of the heart and the veins, he demonstrated certain fundamental facts. One of the important observations was that in most hearts the posterior basal surface of the left ventricle is supplied by branches of the right coronary artery and that when sudden closure of the right coronary artery occurs the resulting infarct is not situated in the right ventricle but involves the

From the Section on Cardiology, The Mayo Clinic, Rochester, Minnesota.

posterior basal surface of the left ventricle. He also demonstrated the differences in the general architecture of the right and the left coronary arteries. The right coronary artery is smaller and more superficial and has gradual ramifications while the left coronary artery is larger and has deep penetrating branches issuing at right angles to the main artery. He also showed that the right coronary artery as soon as it contributed to the supply of the left ventricle lost its architectural characteristics and assumed those of the left coronary artery.

Physiology of the Coronary Circulation

During this span of years, investigators have carried out exhaustive studies dealing with physiology of the coronary circulation. Outstanding among these contributions have been the careful researches of Anrep and his co-workers[1-7] which are so comprehensive that only generalities can be discussed. Experiments were conducted both with the denervated heart-lung preparation and the innervated mammalian heart. Their work clearly showed that in the denervated heart-lung preparation arterial blood pressure was the chief factor influencing coronary blood flow. In this type of experiment no significant change in coronary blood flow occurred during phases of cardiac acceleration. These workers employed the hot wire method and, after slowing the heart by cooling, stimulated the ventricle to contraction by single induction shocks. They concluded that the effect of cardiac acceleration on the coronary blood flow depended on the combined effects of the change of duration and the strength of the resulting premature contraction.

Anrep and his co-workers further demonstrated that the compressing effect of the contracting heart muscle was capable of diminishing coronary blood flow. Increases in coronary blood flow occurring with increased cardiac output in the innervated heart were shown to be of reflex origin for this effect was abolished after section of the vagi. The action of a wide range of drugs on the coronary circulation also was investigated. It was shown that drugs capable of elevating arterial blood pressure also were capable of decreasing coronary blood flow during systole and of increasing it during diastole. Extracts of the pituitary body greatly reduced the coronary blood flow. In progressive spontaneous myocardial failure it was shown that the discharge of blood from the coronary sinus was diminished as much as 30 per cent.

Notable studies have also been contributed by Essex and his co-workers.[22-27,36,38,68] Their various studies have been conducted by means of a thermostromuhr according to the method of Essex, Herrick, Baldes and Mann.[8,25] Using the heart-lung preparation, their conclusions agreed with those of other workers that the coronary blood flow depended greatly on the mean arterial pressure. No effect on coronary blood flow was observed with changes in cardiac output provided the arterial pressure and the temperature of the perfusing medium were maintained at constant levels. Coronary blood flow was increased on an average of about 150 per cent when the cardiac branches of the stellate ganglion were stimulated and this effect was believed in part to result from a vasodilator action of the sympathetic nerves. Contrary to Anrep's belief, Essex and his co-workers were able to demonstrate an increase in coronary blood flow with acceleration of heart rate which was clearly not the result of elevation of the mean arterial blood pressure.

A very interesting group of experiments was conducted on trained dogs with the thermostromuhr in place. Thus, the influence of exercise on the coronary blood flow was investigated. These workers demonstrated that successive increases in the rate of work produced additional rises in blood pressure which were approximately proportional to the rate of work for the individual animals in both the control and the experimental groups. In some instances the blood pressure reached its peak early and declined. In some cases it remained near the peak, while in others it continued to rise throughout the entire period of exercise. The great variations which occurred in coronary blood flow could not be satisfactorily explained by changes in blood pressure alone and these investigators concluded that changes in pulse rate with exercise were usually a better criterion of changes in coronary blood flow than were the changes in arterial blood pressure.

In another series of experiments under the same conditions these investigators studied the influence of various drugs on the coronary blood flow. They concluded that changes in the blood flow in the right and left coronary arteries of the trained dog responded in the same qualitative manner to the drugs administered. Drugs known to lower arterial blood pressure, such as theo-

phylline ethylenediamine (aminophylline), histamine, muscle adenosine phosphoric acid (M. A. P.), acetyl-beta-methylcholine chloride (mecholyl), glyceryl trinitrate and papaverine, when administered in proper doses, caused a marked increase in the coronary blood flow, as much as 200 to 300 per cent in certain instances. With only two exceptions, the action of these drugs, when given intravenously, was of short duration. Anesthesia with pentobarbital sodium (nembutal) in one instance resulted in a prolonged augmentation of coronary blood flow.

Drugs which customarily raise arterial blood pressure, such as pitressin, decreased the coronary blood flow as much as 80 per cent and reduced the heart rate. Atropine increased the coronary blood flow as much as 86 per cent and accelerated the cardiac rate, but had little effect on the arterial blood pressure.

Essex, in collaboration with Herrick and Visscher, investigated the action of certain glucosides of digitalis lanata on the coronary blood flow and blood pressure in the trained dog. The glucosides were injected in doses smaller than those capable of producing retching and vomiting. The mean blood flow in the circumflex branch of the coronary artery was measured. In thirteen experiments, with the doses employed, the digilanids A, B, and C, and no effect on the mean coronary blood flow.

Visscher and his associates in their experimental studies reëmphasized the importance of pressure gradients in the control of coronary blood flow. They showed that the greater the differences in pressure between the aorta and the pulmonary artery, the greater is the thebesian flow, while the coronary sinus flow is reduced. When the aorta-pulmonary artery pressure head is less than 60 mm. of mercury, the thebesian flow subsides greatly. The higher the aorta-coronary sinus pressure difference, the greater will be the coronary sinus flow.

Katz and his co-workers studied the distribution of the coronary blood flow and made important observations regarding the drainage mechanism of the venous blood. They showed that an average of 92 per cent of the blood from the right circumflex artery drains into the right thebesian system, while the coronary sinus receives an average of only 1 per cent and the left thebesian system an average of 7 per cent of the blood. In the case of the left circumflex artery, the right thebesian system drains an average of 48 per cent of the blood, the coronary sinus, an average of 38 per cent, and the left thebesian system, 14 per cent of the blood. The anterior descending branch of the left coronary artery drains an average of 51 per cent of its blood into the right thebesian system, an average of 42 per cent by way of the coronary sinus, and an average of 7 per cent into the left thebesian system. These studies clearly showed the importance of the right thebesian system as a drainage bed, even of the blood from the arteries of the left side of the heart. Thus, approximately as much as two-thirds of the total blood flowing through these three important arteries drains into the right thebesian system and less than a third into the coronary sinus.

Other important contributions include those of Wiggers,[74,75] Fowler, Hurevitz and Smith, Gunn, Gruber and Kountz, and others too numerous to mention.

Pathology of Coronary Disease

Numerous notable contributions dealing with the pathology of coronary disease have appeared in the medical literature of the last quarter century. Outstanding among these studies have been those dealing with both sudden and gradual closure of coronary arteries. The pathologist as well as the clinician has developed an entirely new philosophy regarding the myocardial response to coronary occlusion. In 1918, only six years after Herrick's monumental article, "Clinical Features of Sudden Obstruction of the Coronary Arteries," the medical profession gradually developed a clinical consciousness of this condition, and the occasional diagnosis of that era has been transformed into the routine diagnosis of today.

Considerable interest has been evidenced and numerous investigations have been undertaken dealing with the causes of coronary atherosclerosis. The work of Leary has been especially interesting. This investigator in 1934, after detailed microscopic study in a reasonably large series of cases of coronary atherosclerosis, suggested that the changes could no longer be considered as results of an aging process but, rather, that they represent a disturbance in the lipoid metabolism of the body, and that atherosclerosis belongs to the class of metabolic diseases, such as diabetes mellitus, obesity and gout. Although Leary's hypothesis has not been definitely proved, it has given the profession ample food for thought and

has opened the way for other investigations in this field. The plasma lipoid studies of Barker on obliterative atherosclerotic disease of the extremities and my studies[80,81] on coronary disease have shown the existence of hyperlipemia in many cases. Montgomery and Osterberg called attention to the frequent coexistence of xanthomatosis with hyperlipemia and coronary disease.

White and Patmos, of the Mayo Foundation, conducted a careful histopathologic study of the healing of cardiac infarction. This investigation was of extreme clinical importance because it offered a measurement that enabled the clinician to determine more accurately the length of time required for complete rest of the patients in bed. Infarcts which had been present for from a few hours to several years were studied. This work, unfortunately was never published, but I have repeatedly referred to it in the literature and have accorded full credit to these workers.

They found that when death occurred within two to four hours after coronary occlusion, regions of focal degeneration were present in muscle bundles of apparently normal appearance. In the muscle bundles, however, regions of early necrosis, cloudiness, pyknosis of nuclei and diminution of the transverse striations were demonstrable and there were slight interstitial edema and congestion of the blood vessels. Infarcts of from four hours to five days old exhibited complete necrosis and acute inflammation. The necrotic regions were found to coalesce, and numerous polymorphonuclear leukocytes were seen around the edges. A few lymphocytes, mononuclear leukocytes and extravasated erythrocytes were visible. In infarcts which were two days old, phagocytosis was well under way.

The amount of fat in the necrotic and degenerated muscle cells was found to be increased and karyorrhexis and karyolysis of muscle bundles were marked. Cellular changes, ranging from hyaline to granular degeneration, occurred. Fibroblasts were observed occasionally at the margins of the necrotic portions of the infarcts which were thirty-six hours old, but they were not plentiful except in infarcts five days old. Infarcts from five to twenty-two days old and even older gave evidence of rapid disappearance of the inflammatory reaction and gradual replacement by connective tissue. After twenty-two days, regions of diffuse fibrosis were present. In infarcts which were from four to six months old, condensation and contraction of the fibrous scar were present, representing complete healing.

In a later publication, similar conclusions were reached by Mallory, White and Salcedo-Salgar.

In 1932, Bartels and Smith demonstrated the occurrence of gross cardiac hypertrophy in the presence of healed myocardial infarction, particularly when multiple infarcts had occurred. Subsequent clinical and pathologic correlations have irrefutably supported this contention in spite of the opposition of certain pathologists who persist in their conviction that such hearts have been subjected to the influences of hypertension in spite of completely contradictory evidence.

The same year interest became focused not only on the presence of cardiac infarction but also on the localization of the infarct. Barnes and Ball reported their findings of the incidence and situation of myocardial infarcts in 1,000 consecutive postmortem examinations.

The studies of Blumgart, Schlesinger[15-17] and their associates dealing with collateral circulation have been outstanding and the importance of the method of repair has been well emphasized. They showed that anastomotic communications of less than 40 microns in diameter between various coronary arteries exist in the normal heart, but apparently play only a potential role in the prevention of the sudden and perhaps serious effects of coronary narrowing or occlusion. When marked narrowing or occlusion of coronary arterial tributaries takes place, collateral circulation tends to occur and intercommunicating vessels of up to 200 microns in diameter may be found. Such collateral circulation is capable of compensating for the reduced vascularity resulting from atherosclerotic narrowing or actual occlusion of main coronary arteries, so that the blood supply of the heart remains relatively adequate for a restricted manner of life. Death occurs whenever a sufficiently large portion of the myocardium undergoes ischemia, with or without necrosis, or when other fatal circumstances intervene, such as profound disturbances in rhythm (asystole or ventricular fibrillation) or congestive heart failure. The serious consequences of coronary insufficiency occur when imbalance exists between the nutritional requirements of heart muscle and the factors which permit adequate nutrition to occur.

Paterson and also Nelson have emphasized the role of intimal hemorrhage in producing coron-

ary thrombosis. Hemorrhage from sinusoidal blood vessels which are found near atheromatous plaques is not uncommon. Hemorrhagic lesions of the coronary arteries have recently been studied and reported by English and me.

Diagnosis of Coronary Disease

The era of twenty-five years ago found the medical profession confused regarding the recognition and identification of diseases of the myocardium. A short time previously, the teaching of cardiology had been centered on cardiac murmurs and the minutia of auscultatory findings had obscured the greater issue of clinicopathologic correlations. The universal employment of the term "chronic myocarditis" seemed self-sufficient and countless diagnoses were tossed into this rather meaningless category. Gradually it became evident that specific types of cardiac disease belonged in specific categories and thus physicians found an ever-decreasing incidence of so-called chronic myocarditis and an ever-increasing incidence of coronary disease, hypertensive heart disease and the co-existence of both.

As already stated, Herrick's article on sudden coronary obstruction kindled medical consciousness to this important condition which for many reasons has been destined to become the formidable problem that it is today. Up to this time the diagnosis of angina pectoris included many instances of coronary obstruction. Gradually, the medical literature became charged with an ever-increasing number of splendid articles calling attention to the typical as well as the atypical clinical manifestations of the condition and separating the phenomena from those of the anginal syndrome of coronary atherosclerosis. Among these articles were those of Christian, White and his associates,[28] Gibson, Hamman, and many others.[19,35,40,41,43-48,50,51,62,64,67,84]

Electrocardiography in Coronary Disease

Notable advances have been made in the science of electrocardiography during the last twenty-five years particularly with regard to the correlation of electrocardiographic abnormalities with clinical and postmortem findings.

Although some of the pioneer studies of electrocardiography in coronary disease require modification in view of present-day knowledge, nevertheless they marked significant advances in the evolution of this field. Among them were the studies of F. M. Smith[59] and Willius.[76,77]

In 1920 Pardee[55] accurately described the cove type of T wave change in acute obstruction of the coronary artery and this report did much to stimulate other investigators to amplify the understanding of other changes in the graphic configuration. Parkinson and Bedford's splendid study appeared in 1928 and paved the way for subsequent investigations dealing with the electrocardiographic criteria for the localization of infarcts. These authors showed that the changes in the RS-T segments could be placed in two groups, the T_1 and the T_3.

A year later, Barnes and Whitten demonstrated that it was possible to localize the region of infarction in the left ventricle when certain electrocardiographic alterations were recorded. The T_1 type of electrocardiogram indicated infarction of the anterior surface of the left ventricle, whereas the T_3 type indicated infarction of the posterior basal portion of the left ventricle.

Wilson and his co-workers and Barnes[10,11] also showed the significance of certain changes in the initial deflections of the ventricular complexes in relation to acute myocardial infarction. The Q_1 pattern was found to be associated with acute or healing acute infarction in the anterior and apical portion of the left ventricle and the adjacent interventricular septum while the Q_3 pattern was found to occur with acute or healing acute infarctions in the posterior basal portion of the left ventricle and adjacent interventricular septum.

In 1934,[78] I published the electrocardiographic findings in 2,000 cases of coronary sclerosis with the anginal syndrome. Normal records were obtained in 34 per cent of the cases while the remaining patients displayed one or more significant abnormalities such as T wave negativity, conduction defects, auricular fibrillation and flutter and lengthened Q wave in lead III. The total group comprised patients with and without hypertension and healed cardiac infarction.

This era also witnessed the introduction of multiple thoracic leads. In 1932 Wolferth and Wood [83,84] placed electrodes directly on the anterior and posterior surfaces of the thorax and by their manner of placement recorded the fourth lead directionally opposite to the conventional first lead. This method was quite universally employed until attempts at standardization were made by the Committee[61] for the Standardization of Precordial Leads of the American Heart Association. Differences in the resultant electrocar-

diograms occur when slight differences in the placement of the electrode occur so that the method is fraught with dangers by those not fully aware of the possible technical variations. This phase of the science of electrocardiography can only be mentioned here as a distinct forward step —detailing it would be a study unto itself.

A word of warning here may not be inappropriate. While the science of electrocardiography has made remarkable progress in the last quarter century its more extended use by the medical profession has permitted the development of certain evils. Electrocardiography, like other diagnostic methods, is basically a clinical adjunct and must remain in this order of importance to ensure its perpetuity. Physicians superficially trained in electrocardiography have the inclination to infer clinical diagnoses from the electrocardiogram alone, a procedure which can never be tolerated. They look upon the graphic registration as an all-revealing method which permits them to simplify their diagnostic scheme by according the same interpretation and significance to certain minutia regardless of the cause of the cardiopathy, the state of function of the heart, the physical findings, and so forth. Such destructive influences must be removed in order to preserve the gains which have been accumulated.

Prognosis in Coronary Disease

With the passage of the years and the accumulation of medical experience based on a remarkably improved diagnostic philosophy, the profession has greatly altered its concept regarding the prognosis of coronary disease. This is particularly true regarding sudden obstruction of a coronary artery with acute infarction of the myocardium. Twenty-five years ago it was quite generally believed that the majority of the patients succumbed immediately or soon after the attack.

Gradually studies appeared and indicated that not all patients with coronary thrombosis were destined to die but that many recoveries ensued and even some patients recovered sufficiently to participate actively in life. Among these studies were those of White,[70] Pardee,[56] Ernstene, Levy,[46] Willius and others.[79]

Treatment of Coronary Disease

While countless suggestions have been forthcoming regarding the treatment of coronary disease this chapter still woefully falls short of its mark. Nevertheless, the better understanding of coronary disease in general has permitted the profession to accomplish much in the application of nonspecific measures. I refer particularly to the fuller realization of the necessity and importance of instituting individualized regimens which can be very comprehensive in scope and when adhered to may remarkably safeguard and prolong the life of the individual patient. Therapeutic suggestions, both medicinal and surgical, have been so numerous that space forbids their detailed discussion or bibliographic reference so that only some of them will be mentioned.

The beginning of this last quarter century still witnessed the employment of cervical sympathectomy and its various modifications as well as paravertebral injection of procaine hydrochloride and absolute alcohol. These procedures have gradually but hopefully lost their appeal. Then came the xanthine drugs (vasodilators) such as theobromine, theophyllin, theosin, theobromine-sodio-salicylate, aminophylline, and so forth. These drugs, while apparently beneficial in a certain percentage of cases, fall far short of a therapeutic success. This was followed by the startling advocation of total thyroidectomy for the control of coronary disease and congestive heart failure from other causes. The procedure was based on the premise that the resulting drop in the basal metabolic processes of the body would result in reduced cardiac demands and work. Its proponents soon lost their enthusiasm and the method has now been generally abandoned.

Various operations were then advocated attempting to bring about new circulation to the heart by the transplantation of muscle flaps, omentum, and so forth. More recently, the introduction of talc into the pericardium with the intention of causing adhesions between the visceral and parietal pericardium and thereby increasing the circulation of the heart has been advocated. These procedures, while interesting and ingenious, are obviously still in their experimental phase and must be received with caution.

Other suggestions comprise the intramuscular injection of a tissue extract, radiation of the suprarenal glands and inhalation of trichlorethylene.

NEUROPSYCHIATRY THEN AND NOW

E. M. HAMMES, M.D.
Saint Paul, Minnesota

MINNESOTA MEDICINE was born and christened during the first World War, and is celebrating its Silver Anniversary in the midst of the second World War.

The progress that MINNESOTA MEDICINE has made during this period in its scientific contributions, in its volume of publications and in its continued high ethical standards should be a great source of pride to every member of our State Medical Association. MINNESOTA MEDICINE has been fortunate throughout these years in having as its editors men of unusual professional skill and untiring energy. The editing and publishing committee wants to take this opportunity to express their appreciation to these editors, who have in a large measure been responsible for making MINNESOTA MEDICINE one of the outstanding state medical journals of this country.

During this period, neuropsychiatry, including neurosurgery, has made remarkable progress. The diagnosis and treatment of the various neuropsychiatric disorders has been placed on a higher and more scientific plane than ever before. A more thorough undergraduate training in every field of medicine, including that in neuropsychiatry, has emphasized to the medical profession as a whole the importance of this special field, and has made possible the diagnosis and proper treatment of many of these interesting problems.

The establishment of a psychiatric unit at the University Hospital of the Medical School of the University of Minnesota, in 1937, has given our medical students ample opportunity to observe the various psychiatric disorders, to diagnose them and to note the effect of proper treatment. Prior to that time, clinics in psychiatry were conducted only at the Ancker Hospital in Saint Paul and the General Hospital in Minneapolis. Invariably the clinical material was limited, and the period for observation confined to that clinic hour. There was no time for further study and for the psychiatric and psychologic treatment of the individual patient. This psychiatric unit has filled a very important place in our medical curriculum and has resulted in great benefit to unfortunate mental patients in the state of Minnesota.

The Child Guidance Clinics, established in the various large centers in this state in 1924, have assisted in solving many of the behavior problems, the child delinquencies, the distressing parent-child relationships and other serious childhood conflicts.

The universal application of the chemical and dynamic studies of the spinal fluid, the better understanding of the various neuropsychiatric syndromes associated with endocrine dysfunction, and the more thorough knowledge of the chemical structure and of the electric potentials of the central nervous system have become important cogs in our diagnostic armamentarium.

The advances made in the field of neurosurgery in intracranial and spinal neoplasms, in operations on the sympathetic nervous system and in the treatment of cerebral injuries surpass every other surgical field, not only in scientific ingenuity but also in therapeutic results.

The introduction of lipiodol for the diagnosis of obstructive spinal cord lesions, and the development of the encephalogram and ventriculogram have resulted in earlier and more accurate localization of cord and brain tumors and other obscure cerebrospinal diseases.

The recognition of shock, of the various types of traumatic intracranial hemorrhage and of the depressed fractures in cerebral injuries along with the development of proper treatment, have reduced the mortality rate in this rather frequent accident from 52 per cent to as low as 8 to 12 per cent in some clinics.

During the early era of Minnesota Medicine, the medical profession passed through a period of the indiscriminate use of the various endocrine extracts. Gradually this was placed on a more scientific and rational basis. Today, twenty-five years later, we are in the midst of a vitamin boom, and the public, our patients, are paying an enormous price for this experiment. Undoubtedly the various vitamins are playing an important role in the development and treatment of certain specific diseases, but their indiscriminate use should be discouraged. It has been quite definitely established that deficiency in vitamin B_1 produces polyneuritis and that lack of vitamin B_2 produces pellagra, not infrequently associated with a psychosis. Experimental studies have further demonstrated degenerative lesions in the central nervous system caused by marked vitamin B_1 deficiency. Similarly, alcoholic polyneuritis is evidently due to a B_1 avitaminosis, and not to any toxic effect of alcohol. Treatment along these lines has produced excellent results.

A rich vitamin diet, with emphasis on nicotinic acid, has resulted in prompt recovery from the cutaneous lesions and also the psychiatric manifestations in pellagra. The early encouraging reports in the treatment of progressive muscular dystrophy with vitamin C and of amytrophic lateral sclerosis with vitamin E have not been confirmed in later studies, and no definite progress has been made in the therapy of these disabling diseases. Yungblut believes that vitamin C may play a neutralizing role in preventing virus infections of the central nervous system. He bases his opinion on experimental work done on monkeys in whom paralytic doses of poliomyelitis virus mixed with small amounts of crystalline vitamin C were injected intracerebrally. No paralytic symptoms developed.

In the winter of 1917, epidemic encephalitis first became prevalent on the European continent and gradually involved the entire civilized world. The first cases in Minnesota were observed in the early summer of 1919, and within five years over 4,000 patients had suffered from this disabling disease in this state. Since then extensive studies experimentally and clinically have been unable to determine a definite etiologic factor (a virus infection) or to suggest a prophylactic or immunizing measure or to develop a successful therapy. Benzedrine sulfate, stramonium or belladonna may relieve some of the distressing sequelæ.

In acute anterior poliomyelitis, the results have been just as discouraging except that the recent Kenny treatment offers a more hopeful outlook and a greater number of recoveries. With the introduction of sulfanilamide in 1935, and its allied compounds, remarkable therapeutic results have been obtained in some of the pyogenic infections of the central nervous system. The mortality rate in meningococcus meningitis has been reduced from 45.9 per cent to as low as 9 per cent. The serious sequelæ have also been materially lessened. In a mild epidemic in Great Britain, in 1941, the results were even more favorable. Streptococcus and pneumococcus meningitis have shown similar satisfactory results but not to the same extent. The virus infections, however, remain resistant to this treatment.

With the introduction of salvarsan by Ehrlich, in 1910, the treatment of syphilis was placed on a more rational basis, and the tendency for involvement of the nervous system greatly lessened.

In the treatment of parenchymatous syphilis the various forms of salvarsan were largely replaced by tryparsamide, prepared by Jacobs and Heidelberger in 1917. The various forms of fever therapy, particularly the malarial treatment for general paresis instituted by Wagner von Jauregg in 1918, have materially improved our therapeutic results. Hyperpyrexia induced by intravenous injections of triple typhoid or by electricity, has produced favorable results in various neurological disorders, particularly in acute chorea.

Among other therapeutic measures developed during this period are the addition of dilantin in the treatment of epilepsy, the use of ergotamine tartrate or ergonovine in the relief of at-

tacks of migraine, and Fürstenberg's treatment for Mèniére's disease, which has produced satisfactory results. Fürstenberg's treatment consists mainly in an absolutely sodium chloride free selected diet, with large doses of ammonium chloride in capsules and some mild sedative. In the more resistant cases surgical section of the auditory nerve has proven successful.

The treatment of narcolepsy with benzedrine sulfate has given satisfactory results in relieving the attacks of uncontrollable sleep. Myotonia congenita, with its inability to contract and relax voluntary muscles, has been greatly benefited by the use of quinine hydrochloride, and the marked muscle fatigability due to myasthenia gravis has been relieved and the tendency to remissions increased by the administration of prostigmin and glycine.

The pioneer work of Berger in developing the electro-encephalograph and the resultant studies in normal and abnormal electric activities of the cerebral cortex have increased our knowledge of and our diagnostic ability in many cerebral disorders. Gibbs and Lennox have demonstrated that epilepsy is a paroxysmal dysrhythmia and that the three main types of epilepsy produce distinct abnormal cerebral rhythms. Electro-encephalography also aids in differentiating organic from functional post-traumatic cerebral conditions, symptomatic from essential types of epilepsy and from hysterical convulsions, and in the localization of cerebral neoplasms.

Surgical measures have finally been devised for the relief of pain in many of the chronic neurological disorders. Local alcohol injection or the radical sensory root resection in trifacial neuralgia have given relief to many intense sufferers. Similar results have been obtained in other prolonged neuralgias by the intraspinal section of the posterior roots. The surgical removal of a protruded intravertebral disc has alleviated the pain and allied symptoms in many cases of sciatica. The epidural or subarachnoid injection of absolute alcohol for the relief of pain in metastatic involvement of the nerve plexuses or the spinal cord is a simple and quite effective procedure. In some cases, however, section of the pathways for pain in the spinal cord, as suggested by Spiller, must be resorted to.

The problem of the care and treatment of the psychoses is still a major one, particularly among the military forces during and after a World War period. The recent shock treatments with insulin, metrazol and electricity for the functional psychoses have increased the percentage of remissions and have shortened the period of hospitalization. Sufficient time has not elapsed to definitely determine whether these remissions will be of longer duration and whether the relapses will be less frequent than with previous forms of therapy. That is the ultimate criterion.

In World War I, neuropsychiatric disabilities constituted about 30 per cent of the disabilities from which soldiers suffered. The cost to the Government of caring for these men, disabled from this cause during the war, including treatment, disability allowances and pensions, has been to date approximately $950,000,000, an average of $30,000 per man so disabled. Many of these men are still confined in Government Hospitals and will be so permanently. It has been estimated that 96 per cent of these disabilities were considered to have arisen *not* in line of duty. In 1927 almost 50 per cent of all patients receiving hospital treatment as beneficiaries of the United States Veterans' Bureau were neuropsychiatric cases.

Neuropsychiatric disabilities in the American Expeditionary Forces became so prevalent that General Pershing, in the spring of 1918, cabled Washington, requesting more careful and thorough neuropsychiatric examination before sending soldiers overseas. In Base Hospital No. 99 A.E.F., where the writer had charge of the neuropsychiatric service, many cases were encountered whose family histories revealed a marked neurotic trait or definite evidence of previous personal emotional or psychiatric instability. Experiences in World War I and previous wars have definitely proven that an individual who succumbs to the ordinary stress of civil life is unable to cope with the strict military discipline, exposures, fatigue and emotional strain of active warfare. Many of these individuals would have been able to carry on quite successfully as useful, self-supporting citizens in civil life. To a much greater extent will this be true in the highly mechanized blitz-krieg of World War II. Military service today demands more emotional stability and intellectual activity than ever before.

In the light of these past experiences, the duties and responsibilities of the neuropsychiatrist in this great conflict are multiple indeed.

Fortunately our country today is equipped with a greater number and more highly trained physicians in this special field. More induction boards are able to have their services. A more thorough understanding of the personality make-up of the individual and better methods of examination will undoubtedly result in an Army more thoroughly equipped psychologically, emotionally and intellectually. This will greatly increase the morale of our Army and should materially lessen our war neuropsychiatric casualties. If the leaders of the United Nations will strive as diligently and diplomatically for a just and lasting peace as our soldiers are fighting for an ultimate victory, MINNESOTA MEDICINE will publish its Golden Anniversary journal among more tranquil and happier surroundings.

ENDOCRINOLOGY IN THE LAST QUARTER OF A CENTURY

MAX. H. HOFFMAN, M.D.
Saint Paul, Minnesota

THE term "internal secretion" was first used by Claude Bernard in 1852. About five years earlier Berthold showed for the first time that a substance produced in one part of the body could act on tissue at a distant point. From the time of these earliest observations until the period under discussion, important contributions to the field were not numerous. Outstanding were the names of Graves, Basedow, Gull, Riverdin, and Kocher, in their contributions to the knowledge of thyroid diseases. Pierre Marie described acromegaly and von Mering and Minkowski produced experimental diabetes mellitus by extirpation of the pancreas. Other individuals of importance were Brown-Sequard with his injection of testicular extracts; Gley, whose studies showed a relationship between the removal of the parathyroids and tetany; and the work of Oliver, Schaeffer, and Takamine on the adrenal medullary function.

The above list of names does not at all include all those who made earlier important contributions, but the observations of these men were about all that was familiar to the student of twenty-five years ago. When one realizes that most of what we now know in endocrinology is the result of the investigations of the last twenty-five years, we can easily understand that it is really a new field in medicine. The development that has taken place in endocrinology has not been due to the research efforts of any one group of investigators, but credit must be given principally to the biologist, the physiologist, and the biochemist. Although the contributions by the clinician have been numerous, they have not been as important as those of the other groups. In fact this failure of clinical medicine to keep abreast with the advancement of the other workers has been quite striking.

The Pituitary Gland

Although Pierre Marie described acromegaly in 1886, and Minkowski in 1887 demonstrated its relationship to tumors of the pituitary gland, nothing was known about the mechanism that produced the characteristic overgrowth of bone and soft tissue. Even as late as 1922, Falta, in discussing the condition, enumerated the various theories advanced to explain the acromegalic changes. He stated it to be his belief, on the basis of clinical studies, that the changes are due to the effect of the pituitary gland on growth, but that there was no experimental evidence to confirm that belief. In 1929, Putnam, Benedict, and Teel produced acromegaly in a dog by the injection of a growth extract secured from the anterior pituitary gland. This work conclusively proved that the pituitary tumor of acromegaly produced an excessive amount of growth hormone.

Recent investigation has shown that the pituitary gland possesses several functions other than growth control. At least six hormones have been extracted in recent years.

In 1926, Ascheim and Zondek, and Philip Smith, working independently, discovered that the anterior pituitary gland has a marked effect on the development of the ovaries in mice and rats. This together with the knowledge that extirpation of the anterior pituitary gland in young animals produces dwarfism and sexual infantilism conclusively demonstrated the part played by the gland in sexual maturation.

This sex stimulating hormone (gonadotropic) was found by Ascheim and Zondek in the urine of pregnant women and forms the basis for the test of pregnancy. The hormone found in pregnancy urine was found to be somewhat different, in its effect, from that secured from the pituitary gland itself, and is now believed to be formed in the chorionic tissue. Although it is believed there are two gonadotropic hormones, a follicle stimulating and a second luteinizing hormone, they have not as yet been separated. The gonadotropins have been rather disappointing in their therapeutic effects, although they have a definite but limited place in endocrine treatment. Recent observations with more potent preparations indicate possibly an increased therapeutic usefulness for these substances.

The anterior lobe of the pituitary gland has been shown to produce several other hormones. These are the thyrotropic hormone, the lactogenic, diabetogenic, adrenotropic, and the parathyrotropic factors of the anterior lobe. The isolation of all of these substances together with the growth and gonadotropic hormones is the result of research in this field beginning about 1925. Although the discovery of these hormones have not as yet greatly improved our attempts at endocrine therapy, they have added immensely to our knowledge of pituitary function and endocrine diagnosis.

In the last twenty-five years only one new syndrome has been ascribed to pituitary gland disorder. The condition described by Cushing in 1932 is now known as "Cushing's syndrome" or "pituitary basophilism." Cushing believed the condition was due to a basophilic tumor of the anterior pituitary lobe. The symptoms characteristic of this condition are very similar to those produced by overactivity of the adrenal cortex, and many clinicians do not agree with Cushing that the disease originates in the pituitary gland.

The Thyroid Gland

There was more known about the thyroid gland twenty-five years ago than of any other gland of internal secretion. No significant advances have been made in the last quarter of a century in regard to medical management and diagnosis of diseases of this organ. When Kendall, in 1915, isolated a crystalline substance from the thyroid colloid which he called "thyroxin," it was felt by many that this was not the true thyroid hormone. Recent investigation has not revealed unequivocal evidence that there is any other substance which is responsible for its activity.

An important recent contribution to our understanding of thyroid physiology has been the finding that the anterior lobe of the pituitary gland produces a hormone, or hormones (thyrotropic factor) that affect the thyroid gland. Continuous injections of this hormone in animals can produce exophthalmos and other evidence of Grave's disease. Thus, for the first time, exophthalmic goiter has been produced experimentally. However, antihormones are developed in a relatively short time, and the induced hyperthyroidism regresses.

The significance of the part played by this hormone in clinical exophthalmic goiter cannot as yet be evaluated. It is possible that persistent exophthalmos following subtotal thyroidectomy may be caused by an oversecretion of this hormone.

Parathyroid Glands

Although the parathyroid glands were discovered in 1880, the relationship of the parathyroids to calcium metabolism and tetany was not suspected until 1907, when the pathologist Erdheim noticed that a definite association existed between parathyroid tumors and skeletal decalcification. In 1908 and 1909, MacCallum and Voigtlin conclusively showed that tetany in parathyroidectomized dogs was due to a lower blood calcium. In spite of these observations it was still believed by many that the main function of the parathyroid glands was to detoxify poisons in the body, particularly guanidine.

Definite proof that the function of these glands was to control calcium and phosphorus metabolism and not to detoxify, was available with the isolation of the parathyroid hormone by Hanson in 1924 and Collip in 1925. This hormone is markedly effective in raising the blood level of calcium in hypoparathyroid tetany. Its exact mode of action in altering calcium metabolism is not as yet known.

The anterior lobe of the pituitary gland secretes a hormone (parathyrotropic) that stimulates these glands. It has never been recovered in pure form. No clinical syndrome is attached to alterations of the parathyrotropic hormone al-

hough the osteoporotic changes in Cushing's lisease are supposed to be due to the overpro- luction of this hormone.

Considerable advancement has taken place in he treatment of hypoparathyroidism and its at- endant hypocalcemia. Although the milder cases an be satisfactorily taken care of with calcium lone, the parathyroid hormone and hytakerol ave been very effective in raising the blood cal- ium in the severe cases. Hytakerol, formerly nown as "A.T.10" was first used by Holtz in 1934 and is derived from irradiated sterols. When given orally it has a marked action in raising the blood calcium.

In 1925, Mandl removed a parathyroid tumor n a case of osteitis fibrosa cystica with remarkable results. He first definitely established the rela- ionship between von Recklinghausen's disease of the bones and an overfunctioning tumor of he parathyroid gland. His observations received confirmation from many sources, and much work as been carried out on many phases of hyper- parathyroidism since that time.

The Pancreas

Following the observations of von Mering and Minkowski, in 1889, that diabetes resulted when the pancreas was removed from dogs, numerous investigations contributed to the various aspects of this disease. Although twenty-five years ago it was felt that the islands of Langerhans se- creted the antidiabetic hormone, no method of extracting this hormone from the pancreas was successful because of the autolytic action of its external secretion. In 1920, Barron made the observation that when the pancreatic duct was obstructed, the cells forming the external secre- tion degenerated and the island cells were left intact. From this observation Banting and Best, in 1922, were able to extract from the pancreas a substance which when injected into dogs was ca- pable of lowering the blood sugar. This hor- mone, which was named insulin, revolutionized the treatment of diabetes mellitus. Its use has made it possible for thousands of diabetics to lead comfortable and useful lives. This discov- ery without question has been one of the most important in medical history.

The mode of action of insulin is not clear in all its details. A much debated point as to whether insulin takes part in the oxidation of carbohydrates is still to be settled. Some of the actions of this hormone are very clear, such as the part it plays in the formation and deposition of glycogen in the liver.

The relation between the pancreas and the an- terior pituitary gland has assumed great im- portance since Houssay showed that the pituitary gland has a very definite inhibitory action on the production or activity of insulin.

Following Houssay's observations, Young in 1940 produced severe permanent diabetes in dogs and cats by the injection of extract of the ante- rior pituitary lobe. This type of diabetes simu- lates in many respects the disease as it occurs in humans. No definite evidence has as yet been found to prove that the diabetes mellitus seen clinically is due to pituitary disturbance. How- ever, the diabetes seen so frequently in associa- tion with acromegaly may well be produced by such a mechanism.

The disturbances in fat metabolism associated with diabetes mellitus is not always influenced by the action of insulin. For this reason it is felt by some that the pancreas must secrete another hormone. Dragstad isolated from the pancreas a substance which is called "lipcaiac" that appears to have some action in the mobilization of fat, and, in particular, has an effect in reducing the fat infiltration in the liver in severe diabetes. It has not been very effective according to clinical reports.

The Adrenal Gland

The adrenal is formed by two separate and distinct endocrine organs—the medulla which is not essential to life, and the cortex which is most essential.

The Adrenal Medulla.—Very little advance has been made in our knowledge of the physiology or disturbances of the adrenal medulla in the past twenty-five years. The controversy between Cannon and his followers, and Stewart and Ro- goff, regarding the function and action of the adrenal medulla has never been definitely set- tled. Cannon's emergency theory that contends the adrenal medulla functions only under condi- tions of emotional stress and has little or no function at other times has been generally ac- cepted.

The Adrenal Cortex.—In one of the master- pieces of medical literature Thomas Addison in 1855 described the symptom-complex now known as Addison's disease. He noted the association of

this syndrome characteristic of the disease with pathological changes in the adrenal gland. Little of importance has been added since that time, either to the clinical picture or essential pathological disturbances. In recent years we have learned a great deal about the physiology of the adrenal cortex and its abnormal functioning in Addison's disease, and also about the therapeutic management of this condition. All of this has come about in the last fifteen years.

Baumann, Kurland, and Marine showed that the blood of adrenalectomized cats had a low sodium and a high potassium content, and that the administration of sodium prolonged their lives. Later it was shown that individuals with Addison's disease showed the same blood findings, and if the sodium intake was lowered, a critical condition was produced. Thus it was shown that one of the functions of the adrenal gland was to prevent a loss of sodium and water through the kidneys, and to control the excretion of potassium.

These observations have led to important diagnostic and therapeutic advances in the management of adrenal cortical insufficiency. The salt deprivation tests in doubtful cases has considerable value, and the low potassium and high sodium diet is usually very effective in treatment.

The importance of the adrenal cortex in carbohydrate metabolism is now receiving greater appreciation than ever. It is probably the main organ concerned with the conversion of proteins into carbohydrates (neoglucogenesis).

Its antagonism to the action of insulin is demonstrated by the sensitiveness of patients with Addison's disease to the action of insulin.

No single hormone has been isolated from the adrenal cortex that is capable of producing all of its effects. For that reason some believe that this gland produces several hormones, one, for example, which effects the electrolyte metabolism and another which acts on the carbohydrate metabolism. A third hormone also is present which will be discussed later.

The adrenal cortical extracts produced in 1928 by Hartman, Pfiffner, Swingle and others have definite effects on the water, electrolyte and carbohydrate metabolism. These extracts are now available commercially but have limited value because of their low potency and high cost.

One of the numerous substances isolated from the adrenal cortex is desoxycorticosterone. Its effect is almost entirely on water and electrolyte metabolism. In 1937, Reichstein synthesized this substance and it has proven of immense value in the treatment of Addison's disease. The present trend of investigation indicates the possibility that we may have in the near future a preparation more satisfactory than anything that we now possess.

The Adrenal Genital Syndrome.—In 1910, Alpert noticed the frequent association between general hirsutism and adrenal cortical tumors. This observation has since been noted many times. There is now ample evidence that the adrenal cortex is in some way concerned with sexual development. Its mode of action is not well understood. The masculinizing sex hormone produced by this gland is known as dehydroisoandrosterone and is related chemically to the other androgens such as testosterone and androsterone. Unconfirmed reports indicate that this substance might be the precursor of testosterone and that the transformation takes place in the testis. In conditions of sex reversal changes associated with adrenal tumors very large amounts of this hormone are found in the urine.

The adrenal cortex also produces an estrogen and several cases of feminization in the male have occurred in association with adrenal cortical tumors.

The Gonads

Certainly the earliest endocrinological observations must have been the effects of castration in the male. As was mentioned before, the conclusion of Berthold that the testis produced a secretion capable of altering the cocks comb was the first evidence of hormone activity. Little knowledge was forthcoming regarding sexual development or gonadal physiology until P. E. Smith, in 1926, showed that following hypophysectomy, the gonads atrophied, and that this atrophy could be prevented by implantation of anterior pituitary tissue.

Following these observations a great deal of work by numerous investigators led to the isolation of a pituitary hormone that was effective in stimulating the activity of the gonads. Later it was found that a pituitary-like hormone could be secured from pregnancy urine or from the blood of pregnant mares. This hormone differs in some respects from that secured from the gland itself.

Further research on the relationship between

ıe gonads and the pituitary gland has established ıe importance of the pituitary in its effect on ɔrmal and abnormal physiology of the gonads. 'he relationship is reciprocal in nature, the go- adal secretion acting in an inhibitory manner on ıe production of the gonadotropic hormone. 'ollowing the reduction of gonadal activity such s in castration or menopause, there is an over- roduction of gonadotropins. This is supposed to e responsible for the disturbances that occur in ıenopause.

The Ovary.—Until recent years our informa- ıon regarding the normal and abnormal func- ıoning of the ovaries was practically nil. There s much still to be learned, particularly regarding ıenstrual abnormalities and uterine bleedings of arious types, and their relation to ovarian hor- ıone disturbances.

Our present knowledge of the hormones which ontrol menstruation has been acquired in the ɔast ten years. Allen and Doisey in 1922 first howed that a substance could be extracted from he ovary which could establish an estrus cycle n castrated rats. In 1927 Ascheim and Zondeck lemonstrated this substance in large amounts in he urine of pregnant animals. In 1929 Doisey nd Butenandt independently crystallized this ıormone and prepared the field for chemical dentification of the estrogenic hormones. The strogen estradiol has been isolated from the fol- icle, and is presumed to be the active ovarian strogen. This hormone is capable of producing ɔnly the proliferative or first phase of the men- strual changes in the endometrium. The second ɔhase or the secretory stage is brought about by he hormone of the corpus luteum.

The main therapeutic usefulness of the estro- genic hormone has been in the treatment of the menopausal syndrome and in this condition it has been most valuable.

The substance produced by the corpus luteum, which exerts the specific effect on the endo- metrium, was first extracted in 1929. In 1934 several investigators simultaneously produced it in a pure form and revealed its chemical struc- ture. It is now produced synthetically and known as "progesterone." It has been used with some success in habitual and threatened abortion and also in various types of uterine bleeding.

The two hormones, estrogen and progesterone, when used in adequate amounts at the proper in- terval, can produce in the uterus the entire men- strual cycle.

The Testis.—McGee, in 1927, extracted from the bull's testis a substance with comb growth properties. In 1931 Butenandt succeeded in pre- paring in a crystalline form the male sex hormone from human urine. Previous to that time nu- merous unsuccessful attempts were made to pre- pare an active male sex hormone. Later, in 1934, Laquer isolated the same hormone from the testis itself. This hormone has been given the name "testosterone." Whether this is the only hormone produced by the testis is still open to question. As yet, however, no other has been found. Sev- eral other substances with androgenic action but inferior in their potencies to testosterone have been found in the urine and adrenal cortex. However, it is now definite that the testis is the main source, if not the only one, of testosterone.

This hormone now produced synthetically is capable of restoring the secondary sex characters resulting from loss of testicular function. It can bring about sexual maturation in the undeveloped male if given in adequate amounts. The clinical field of usefulness for this preparation is, how- ever, rather limited.

This review of the developments in endocrin- ology in the last twenty-five years is in no sense a complete compilation of all the work that has gone on in recent years and which is being car- ried out at this time. Such a task would be enor- mous. An attempt has been made to mention the most important contributions, but even here the work of many investigators who have added significantly to our knowledge has not been touched upon.

AWARDS ESTABLISHED TO FURTHER RESEARCH ON CELLS

Creation of two new prize awards for research adding to knowledge of factors affecting the growth of cells with particular reference to human cancer is an- nounced by Dr. William J. Robbins, chairman of the National Science Fund of the National Academy of Sciences. The prizes are to be known as the Charles L. Mayer Awards.

"One prize of $2,000 will be awarded for a contribu- tion published in 1942 or submitted in manuscript to the National Science Fund," Dr. Robbins stated, "and a similar prize in 1943. The Charles L. Mayer Awards are a new type of award in that they will be given to further the scientific work of the recipient. They are not only rewards for past accomplishments but are also de- signed to increase the opportunities of those with excep- tional abilities to carry on further research."—*Science News Letter,* December 5, 1942.

PREVENTIVE PEDIATRICS IN PRIVATE PRACTICE

E. J. HUENEKENS, M.D.
Minneapolis, Minnesota

A DISCUSSION of the progress of pediatrics in the past quarter century could be developed from several different angles. Many or all of the following samples might well be headlined as leaders in such progress. Stress might be laid on the recent discoveries in the diagnosis of epilepsy (electro-encephalography) or its treatment (dilantin). One might dilate on the newer knowledge of the anemias of the newborn and their treatment. Also we are on the verge of a better understanding of asphyxia neonatorum with a growing concept of the dangers of maternal anesthesia and analgesia to the newborn infant. As another sample we have found that the administration of Vitamin K immediately after birth will control many of the hemorrhagic diseases of the newborn. Again the death rate among premature babies has been dramatically reduced by improved care and feeding and the wise use of air conditioned surroundings. The great advances wrought in the treatment of various acute infections by the sulfonamides might well be considered the most important event of the last twenty-five years. Finally, one might nominate as the outstanding advance in pediatrics today what Powers[3] calls supportive therapy. In a paper entitled "Developments in Pediatrics in the Past Quarter Century," he says:

> "By supportive therapy I mean procedures which might be termed physiological treatment since they are directed toward correcting physiological disturbances rather than to eliminating causes of disease. I refer particularly to the use of parenteral fluids such as blood, blood serum, and normal salt, special electrolyte, and glucose solutions. Now, as never before, we realize that a baby can tolerate tremendous physical trauma but he cannot endure fluid and salt deficits without exhibiting the train of serious symptoms we associate with the terms dehydration, electrolyte imbalance, and shock."

In the long view, great as these advances are, preventive pediatrics is of even greater importance and will perhaps blaze a path for other branches of medicine to follow. The increase in life expectancy in the last twenty-five years is due, in large part, to the decrease in infant mortality. In Minnesota the infant death rate has fallen from 70.1 in 1915 to 33.3 in 1940. The drop in the mortality of infants under one month of age (the neonatal period) has remained virtually stationary during that time, while practically all reduction has been from the ages of one to twelve months. Our increasing knowledge of nutrition and other prophylactic measures must be credited with the largest part of this reduction.

Modern medicine is stressing more and more the prevention of disease. Many phases of prevention must be performed by public health agencies, but there remain a large number which can best be conducted by physicians in private practice; though I admit the majority of physicians are not alert in carrying them out. Partly this is due to the neglect of our medical schools in teaching prevention in private practice. The average doctor persists in thinking that the care of the sick is his sole function. I have heard medical men on many occasions scoffing at well-baby care by pediatrists as a "racket." It is common to hear an old-fashioned doctor query, "Why vaccinate against smallpox or inoculate against diphtheria when there is no epidemic?" Several years ago the Community Health Service made a survey of the cases that had been discharged from its clinics because the financial situation of the parents had improved and they were able to pay a private physician for well-baby care. As a result of this survey the organization was forced to conclude that most general practitioners do not appreciate the importance of regular and complete physical examination of the well child. Some of the comments of the mothers were quite illuminating: "My doctor weighed the child only. We feel we cannot afford to pay $2.00 for weighing the child when we can get that done down at the corner store." "When I took my child for vaccination and inoculation for diphtheria he said to wait until the child reached school age." One mother had to ask the doctor if he did not want her to undress the children. His reply was, "No, they look fine." A very common comment from the doctor is that he was too busy to bother with well children.

I presume that the attitude of medical practitioners all over the country does not differ very much from the samples I have just quoted. Out-

side of the pediatrists and a few internists, prophylaxis, in private practice, is in its infancy. If practicing physicians do not wish to have governmental agencies take over more and more of their work, they must seize the opportunity to do preventive work in their private practice. My purpose is to tell you how this can be done. The value of preventive medicine varies inversely in proportion to the age group, the younger the child the more valuable the prophylactic efforts. It is good pediatric practice to have the infants brought in for an examination and advice once a month for the first ten months of life, then every two or three months until the child is two years of age, twice a year until the child is five, and thereafter for annual visits.

During the first months of life our principal function is to direct the feeding and nutrition of the infant. The baby should be weighed each time and we should expect an average gain of 5 ounces a week for the first six months of life and 4 ounces for the second six months. The mother should be encouraged to nurse her baby. It has become rather fashionable of late years to decry the importance of breast feeding, but while greater advances have been made in artificial feeding, in the great majority of cases there is no food to equal nature's own. After the first three months of life an expert pediatrist can do almost as well with artificial food but it must always be borne in mind that breast feeding, whether expertly directed or not directed at all, is equally good feeding while the value of artificial feeding depends entirely on the expertness of its direction.

The best mortality statistics on breast fed and artificially fed infants are those made by Woodbury[4] on 22,000 live born infants in eight American cities. His summary is as follows:

"The analysis has shown that artificial feeding, as actually practiced in typical city populations, is associated with a mortality between three and four times as high as the mortality among breast fed infants. This excess mortality is not to be explained by the slight overweighing of the group of artificially fed infants in certain groups characterized by high mortality rates; and it appears in all nationalities and in all earning groups."

If the amount of mother's milk is becoming inadequate it can be increased by nursing the baby oftener, by nursing on both breasts each time, and above all by completely emptying the breasts after each nursing. This last can be accomplished by employing a hand pump, water or electrical pump, or by teaching the mother manual expression. If, in spite of these efforts, there is insufficient milk, artificial food should be given after each nursing rather than to replace a nursing. When artificial food becomes necessary, simple dilutions of boiled milk with carbohydrate additions, or evaporated milk dilutions may be used. Only in exceptional cases is it necessary to employ more complicated formulæ. In the first six months of life the baby requires, on an average, 45 calories for each pound of body weight in twenty-four hours. In terms of both breast milk and cow's milk this means two ounces for each pound of weight.

To prevent scurvy, the baby should be given early one teaspoon of orange juice to be gradually increased to three ounces a day. Antirachitics should be employed from the second week of life. Two teaspoons of a potent cod-liver oil daily is sufficient to prevent rickets in the majority of cases, though with increasing war shortages it may be advantageous to employ concentrated substitutes such as viosterol and oleum percomorphum. The infant should be examined monthly for signs of rickets or anemia; this is especially necessary in prematures. A large proportion of infants exhibit early evidences of a sensitive skin. Such infants should be protected from all external irritants such as woolen underclothing, cold, soap and hard water. Appropriate lotions and ointments may be used to prevent the appearance of eczema. When eczema persists, it may be necessary to employ an elimination diet. From the fourth to the twelfth month vegetables, cereals, cooked fruits, and egg yolk may be added to the diet, and by the tenth month the infant may be placed on three meals a day.

During the latter half of the first year the infant should be immunized against various diseases. Sauer's pertussis vaccine may be given any time after six months of age. When exposed to whooping cough 10 per cent of infants who have been given this vaccine may contract a mild pertussis as against 75 per cent of those nonimmunized. Such results warrant us in advising these immunizations though it must be made clear that the results cannot be guaranteed. The three-dose diphtheria toxoid should be administered at eight months of age to be followed in

four months by the Schick test. Tetanus immunization may be employed for any child but it is of especial benefit to allergic children since they are likely to be more sensitive to horse serum.

Vaccination against smallpox should be performed before the end of the first year. The reactions of the infant to all these procedures is exceedingly mild; much milder than in older children and adults. Typhoid and scarlet fever immunizations may be done later if special circumstances warrant.

From the second to the fifth year infection plays an increasingly important role in the child's life. It has been said that the greatest unsolved problem of pediatrics is how to prevent recurring and chronic upper respiratory infections. Ultraviolet radiation and large doses of Vitamin A have been recommended but they are only mildly effective. So-called "cold" vaccines may be administered but only when all other methods have failed. Our principal weapon remains, the removal of foci of infection. In childhood such foci are limited almost entirely to tonsils, adenoids, and accessory nasal sinuses. The deciduous teeth are frequently a source of local infection but very seldom of focal infection. The question of when to remove tonsils and adenoids and when to invade sinuses has caused more controversy than perhaps any other medical and surgical procedure. The indications for tonsillectomy and adenoidectomy are: (1) obstruction to breathing; (2) repeated or chronic infections of the upper respiratory tract; and (3) infection in remote parts of the body which probably originate from a focus in the nose and throat. Such infections are: otitis media, recurrent or chronic bronchitis, rheumatism, infectious asthma and nephritis.

The relation of focal infection to systemic disease is no more clear cut than in otitis media. Drainage of the maxillary sinuses is the operation of choice for recurring otitis media and even in subacute and chronic otitis media. It has been a surprise to me how frequently drainage of sinuses has relieved a more or less chronic otitis media and made a mastoid operation unnecessary. If there is no emergency involved I always insist on a sinus drainage before a mastoidectomy is permitted. From personal experience over a period of years I recommend this procedure very highly even though it has received little consideration in medical literature. Even if mastoidectomy is necessary after sinus drainage, the removal of foci of infection will help prevent further mastoid disease, which is quite possible after a mastoidectomy.

The relation of foci of infection to the rheumatic syndrome has been an important controversy for years. Infections of the nose and throat are probably not the true cause of rheumatism but are frequently the immediate exciting cause. When such is the case the tonsils and adenoids should be removed and if this brings no relief, sinus drainage should seriously be considered. Kaiser of Rochester has written many papers to show that tonsillectomy does not prevent rheumatism and probably does little to alleviate it after it has begun. I accept his work as sound but feel that only part of the problem has been attacked because the sinuses have been completely ignored. In Kaiser's work, and in similar statistical studies, the answers are all recorded as definite success or failure. In my experience removal of foci of infection markedly alleviates the rheumatic condition. But in a statistical study such cases are recorded as failures if even mild rheumatic attacks recur. The relation of infection to rheumatism is nowhere more completely demonstrated than in the successful prophylactic use of sulfanilamide in these cases. It would therefore seem logical to supplement such prophylactic therapy by the removal of foci of infection. This is another important field where the sinuses have been largely overlooked as a source of infection.

In recurring bronchitis, chronic bronchitis, and bronchiectasis the sinuses are an important source of infection. It is especially in these cases that allergy must be ruled out and this is not an easy thing to do. The seriousness of chronic bronchitis and early bronchiectasis is so great that the patient should usually be given the benefit of any doubt and the tonsils and adenoids removed but even more important the maxillary sinuses should be drained.

Acute glomerular nephritis in childhood is practically always secondary to an acute infection elsewhere. Fortunately the prognosis is usually good, but in most cases it is sound practice to remove the tonsils and adenoids and if indicated drain the sinuses after the disease has subsided, to prevent recurrence. Occasionally where convalescence is unduly prolonged focal infection removal might be indicated while the disease is still active.

Sinus disease must be considered as a possible

factor in such diverse conditions as certain types of pyuria, which recur only in connection with upper respiratory infection; children who have convulsions with each recurring bout of fever; cases of abdominal pain which simulate appendicitis but which on careful observation can be shown to be due to upper respiratory infection; and in a few cases of asthma where infection is the exciting cause.

The best judge of the indications for a tonsillectomy is not necessarily a nose and throat specialist, but rather the physician who has been seeing the child at regular intervals during his respiratory infections and one who is capable of making a complete physical examination. The expert examination of the nose and throat is of less importance. The sanest views on the tonsil problem are contained in an article on the "Indications for Tonsillectomy" by L. W. Dean.[2] Among other things he says:

"Rules cannot be made to determine when tonsils should be removed, the good judgment of the physician must decide in each case just what should be done. He must take into consideration the local conditions, the condition of neighboring structures, and the general condition of the patient. The tonsils play a much more important role as a source of infection in children than in adults."

If the removal of the tonsils does not solve the problem there are other foci of infection remaining, most often in the maxillary sinuses. The point I wish to emphasize is that the physician, be he pediatrist or general practitioner, who examines the child regularly and not just when he has acute infections is in a better position to make a sane, sound judgment regarding the removal of focal infection than the experts who see the patient only once or twice and form their opinion solely from the local nose and throat viewpoint.

Finally, periodic examinations must concern themselves with the emotional side of the child's life, which is undoubtedly fully as important to his future happiness as his physical health. I would like to emphasize that the child must be shown enough love by his parents to acquire a feeling of security but not so much love and sympathy that he leans on it too heavily and is afraid to venture into the world where this crutch will be absent. Adler says that such smothering love and overprotection is the principal cause of the inferiority complex. The family physician or pediatrist is in the best position to advise parents about the emotional side of a child's life because the parents naturally consult him and are accustomed to accepting his advice. Thus he may nip the difficulties in the bud by inducing the parents to change their attitude or when this is impossible, by having the child enter a nursery school. This last may sound formidable, but I would stretch the term nursery school to include private homes where a minimum or four or five pre-school children may get together and have supervised and group play. Difficult social adjustments of the future may be prevented by exposing the child to the "give and take" contact with his equals away from the soft shelter of his own home. As great a psychiatrist as Freud was one of the first to appreciate the value of nursery schools in preventing future emotional imbalance.

The common symptoms of poor appetite, sleeplessness, tantrums and fears rest largely on an emotional basis. By correcting in early life the environmental factors which bring about these comparatively mild neuropathic conditions, we may save the child from the delinquency of adolescence and the so-called nervous breakdowns of adult life. It has been said that the emotional pattern of a child's life has been fixed by the time he is five years of age. If this is true (and it is approximately so) then the pediatrist and the family physician can accomplish more in prophylactic mental hygiene than the psychiatrists and their clinics. The famous German pediatrist Czerny recognized this thirty years ago when he published his book "Der Arzt als Erzieher des Kindes" ("The Physician as a Guide to Bringing up Children").

Of the many books on child psychology on the market I wish to recommend two that are noted for their common sense attitude; Thom's "Everyday Problems of the Everyday Child" and Cameron's "The Nervous Child." Last but not least, every physician who deals with children should read Brennemann's[1] "The Menace of Psychiatry," as instructive and entertaining an article as ever appeared in a medical journal. Books on modern psychology and psychiatry have glutted the market for years; Brennemann in this bit of special pleading takes issue with them on a number of important points and pleads for a return to common sense in our dealings with children.

In conclusion, I hope I have pointed out the possibilities of preventive pediatrics in private practice. The effectiveness of this supervision

will depend on the skill, the knowledge, and the experience of the practitioner. If we physicians do not possess sufficient skill, we must acquire it as one of the necessities of modern medicine.

THE DEVELOPMENT OF CLINICAL PATHOLOGY AS A SPECIALTY

ARTHUR H. SANFORD, M.D.

Rochester, Minnesota

DURING the last quarter of a century specialization in medicine has developed in a most remarkable fashion. Among the specialties now recognized is that of clinical pathology. Although a number of laboratory men who would now be considered qualified clinical pathologists were practicing this specialty before 1918 when MINNESOTA MEDICINE came into being, their position in the field was not well established. The specialty as now defined by the American Board of Pathology is that branch of pathology that deals with bacteriology, immunology, biochemistry, parasitology, hematology, and clinical microscopy in relation to the diagnosis, prognosis and treatment of clinical disease. In addition to this, many clinical pathologists include in their daily work the diagnosis of biopsy material or surgical pathology. They may be qualified also as specialists in pathologic anatomy.

In the first volume of MINNESOTA MEDICINE, published in 1918, is a paper on "Absolutely Necessary Microscopic Diagnoses," by W. C. MacCarty, which he read before the meeting of the Minnesota State Medical Association. He emphasized the necessity of adequate training in laboratory fields and that the pathologist should be considered a consultant. Marx White in discussing the paper expressed the belief that the scarcity of whole-time laboratory men was principally and largely due to the inadequate compensation given to such men and the fact that clinicians did not correlate their work with that of laboratory men. This paper is mentioned because of the great impetus to the recognition of clinical pathology as a specialized field that came after the formation of the American Society of Clinical Pathology three years later in 1921. Dr. MacCarty was the second president of this society and there have been two other presidents from the State of Minnesota, Dr. A. H. Sanford in 1927-1928 and Dr. T. B. Magath in 1938-1939. The president in 1939-1940 was Dr. L. W. Larson of Bismarck, North Dakota, an alumnus of the University of Minnesota, School of Medicine. The objectives of this society are the promotion of the practice of scientific medicine by a wider application of clinical laboratory methods to the diagnosis of disease; the stimulation of original research in all branches of clinical laboratory work; the establishment from time to time of standardization for the performance of various laboratory examinations; the elevation of the scientific and professional status of those specializing in this branch of medicine and the encouragement of closer coöperation between the practicing physician and the clinical pathologist. That there has been a measure of realization of these objectives I firmly believe.

A brief description of the progress that has been made in this field during the last quarter of a century may interest the readers of MINNESOTA MEDICINE. I do not believe that I make any overstatement of facts in the contention that much of the progress has been due to the activities of the American Society of Clinical Pathologists. One of its active members, Dr. Warren T. Vaughan, succeeded his father, Dr. Victor C. Vaughan, as editor of the *Journal of Laboratory and Clinical Medicine*. This journal has been in existence two years longer than MINNESOTA MEDICINE and its volumes record the introduction and development of many of the laboratory procedures that have become routine in an up-

From the Division of Clinical Pathology, the Mayo Clinic, Rochester, Minnesota.

to-date clinical laboratory. The American Society of Clinical Pathologists, since 1931, has published the widely read *American Journal of Clinical Pathology*. Dr. Magath was the able editor of this journal for the first six years of its existence. Advances in the field of clinical pathology are not made necessarily by the clinical pathologist but rather are made for him by investigators in the fields of physiology and clinical medicine; however, the actual worth of new procedures finally is tested by their routine use in clinical laboratories and by comparison of the results reported by clinical pathologists.

In the field of hematology the well recognized development is due to the better understanding by both clinicians and clinical pathologists of the methods of cytologic study and the management and treatment of diseases of the blood and blood-forming organs. Through the teachings of Dr. Hal Downey and his colleagues and former students, the careful preparation of blood films and their staining for study have been greatly improved. Innumerable articles on hematology have appeared in all medical journals during the past quarter of a century. Some of the interesting papers on this subject that have appeared in Minnesota Medicine are as follows: In 1927 E. T. F. Richards wrote on "Infectious Mononucleosis"; in this paper he covered his experience during the period back to 1921. In the same volume an editorial on "Glandular Fever (Infectious Mononucleosis)," appeared which contained the statement that the question as to which term is proper is for the hematologist to settle. Six years later, in volume 16, R. C. Logefeil reported a case of "Acute Mononucleosis or Glandular Fever." He stated that the case was reported because this disease was more common than generally recognized; he reëmphasized the importance of careful morphologic study on blood cells when diseases were present which involved any part of the hemopoietic system. This paper was read at one of the early meetings of the Minnesota Society of Internal Medicine. In 1930, in volume 13, C. H. Watkins and F. J. Heck published a paper read at a meeting of the Minnesota State Medical Association on "The Practical Value of Examination of Blood Smears." In volume 14, R. C. Logefeil reported a case of agranulocytic angina and stated that seventy-nine cases of undoubted agranulocytic angina had been reported in the literature at that time. Two years later in volume 16, E. T. F. Richards and Kano Ikeda published a paper on "Agranulocytosis." In volume 23, J. M. Adams and R. F. Cochrane published a paper on "Erythroblastosis (Icterus Gravis) in the Newborn." They recognized the high familial tendency in this disease. However, this was before the rôle of the Rh factor as a possible cause was considered. In volume 22 appeared an editorial on "The Megakaryocyte" with several good references to the literature of 1938. In that editorial reference is made to the statement by Castle that Hodgkin's disease is a megakaryocyte tumor. The whole study of the megakaryocyte was directed toward determining the value of examinations of bone marrow as a clinical laboratory procedure.

In the field of serology, although there has been no real change in the basic methods, a remarkable development in modifications of the complement fixation tests and of the flocculation tests has occurred in the last twenty-five years. In volume 1, J. H. Stokes wrote in an article entitled "Medical Coöperation in the Problem of War Syphilis" as follows: "If the negative Wassermann is destined to yield in some degree to clinical judgment, the positive Wassermann must, in its turn, have a restoration to medical confidence." At that time, the Army serodiagnostic test was based on the Noguchi and Bronfenbrenner antihuman hemolytic system. This was not a particularly sensitive test. In 1922, the Kolmer modification of the Wassermann technique and the careful studies concerning the preparation of various reagents were developed. At the same time, the Kahn flocculation test became a much favored method for the serodiagnosis of syphilis. In volume 10, Margaret Warwick wrote an editorial on "The Kahn Precipitation Test for Syphilis." This was in 1927. She stated, "It may not be too presumptuous to predict that in the not too distant future it may entirely supersede the old Wassermann reaction in the laboratory diagnosis of syphilis." Fifteen years later it is interesting to note in this connection that although this and other flocculation tests are considered extremely valuable, it is not believed that they should supersede the complement fixation test but rather should be used in conjunction with it. Shortly after the development of the Kahn test, Kline described his microscope slide precipitation

test and Hinton developed a highly satisfactory flocculation test requiring overnight incubation in the water bath. This along with the Eagle flocculation test and the Eagle complement fixation test became a standard test in this country after the 1935 evaluation of serodiagnostic tests for syphilis, conducted by a joint committee of the American Society of Clinical Pathologists and the United States Public Health Service.

In the selection of donors for transfusion, there was considerable confusion owing to the numerical designation of the four blood groups. The various societies concerned, including the American Society of Clinical Pathologists, suggested that the letters AB be substituted for group I of the Moss classification, A for group II, B for group III and 0 (zero) for group IV. Fifteen years ago in an editorial in MINNESOTA MEDICINE, I suggested that the reports could be made in such a way that these letters were included in brackets after the numbers. Use of the numbers has ceased, and in the literature and in reports from the laboratory to the clinician, groups are referred to only by the letters AB, A, B and 0. This classification was proposed by Landsteiner, the discoverer of blood groups. The demonstration of M, N and MN groups is of academic interest and also of practical use in medicolegal cases, but by far the most important new investigations on the blood are in relation to the Rh factor. To this factor apparently can be attributed many unexplained reactions after transfusions with blood of the correct group and it also provides a most striking explanation for the cause of erythroblastosis.

In the field of bacteriology the diagnosis of undulant fever by use of agglutination tests and also cultures of blood for the organism has been a development of the past quarter of a century. Recognition of the importance of this disease began to appear in MINNESOTA MEDICINE in volume 12 in an article by F. J. Hirschboeck presented at the meeting of the State Association in 1929. In the same volume R. W. Giere reported a case of Malta fever. He referred to Evans' report in 1928 of sixty-five cases. Also in this same volume, C. O. Kohlbry reported a case of undulant fever of an infant, one year old. In volume 13, E. C. Bayley had an article on the same subject. In volume 14, A. C. Fortney reported four cases. In volume 16 was published the address on "Undulant Fever (Brucelliasis)" which Walter M. Simpson read before the meeting of the State Association in 1933. At that time he stated that during the past five years undulant fever had evolved from the obscurity of a clinical curiosity to the prominence of a permanent public health problem. Eight years later in volume 24, another address by Simpson on the same subject appeared; it also was presented before a meeting of the State Association. In the same volume, I. Fisher published a paper on "Brucellosis."

During the same period, tularemia became recognized as an important disease and its diagnosis is made in a similar manner by agglutination test and by culture. An editorial by Margaret Warwick in volume 11, 1928, brought attention to Simpson's report of the appearance of tularemia in Dayton, Ohio. In volume 16, in 1933, H. R. Hartman, D. C. Beaver and F. G. Green reported on "The Occurrence of Tularemia in Minnesota in 1921: Report of Two Cases—One Fatal with a Necropsy Report." E. C. Hanson and R. G. Green also had reported on "Tularemia in Minnesota" in the *Journal of the American Medical Association* for June 8, 1929. By 1932 the number of cases in the State Department of Health of Minnesota made it evident that tularemia had become of epidemiologic significance in Minnesota. Probably the first case in Minnesota was reported in MINNESOTA MEDICINE in 1927 by L. H. Rutledge from Becker County.

Another disease which is diagnosed chiefly by an agglutination test is that of Rocky Mountain spotted fever. An editorial in volume 15 in 1932 brought attention to the appearance of this disease in Minnesota and to the use of the Weil-Felix reaction for confirmation. In 1936, H. A. Reimann published an article in volume 19 on "Rocky Mountain Spotted Fever in Minnesota: Report of the Second Indigenous Case and Biologic Studies." He emphasized that biologic and bacteriologic tests were necessary for diagnosis.

It is impossible to mention in detail all of the various improvements in technical procedures for the culture of organisms, both aerobic and anaerobic, that have been developed in the last quarter of a century. The preparation of media of all sorts has been greatly simplified by the accurate preparation of media and the marketing of them in a dehydrated state. Numerous modifica-

tions of culture media have increased the reliability of differential diagnoses in the field of bacteriology as performed in the clinical laboratory. The demonstration of acid-fast bacilli stained with auramine O by fluorescence microscopy is perhaps the most recent development in the examination of sputum and other materials for *Mycobacterium tuberculosis.* Within the last few years there has been an increasing interest in histoplasmosis, caused by *Histoplasma capsulatum,* now known to be a fungus disease. Torula meningitis, caused by an organism classified by Todd and Herman and confirmed by A. T. Henrici as *Debaryomyces neoformans,* is receiving an increasing amount of attention in clinical laboratories. The same may be said for infections with *Coccidioides immitis.*

Parasitology, as a special field in zoölogy, requires highly specialized training and has a history which is older than that of bacteriology, as many protozoal parasites were discovered before pathogenic bacteria were known. During the past twenty-five years, parasitology has been of continued and increasing interest in the clinical laboratory. Minnesota Medicine has contributed its share to the literature of importance in this field. In volume 10 an editorial on "Infected Fish" referred to an article in the same volume by T. B. Magath on "Experimental Studies on *Diphyllobothrium latum.*" This was a preliminary report. In the next volume, R. O. Christenson and W. P. Greene reported "Studies on Biological and Medical Aspects of 'Swimmer's' Itch." This was the first report of schistosome dermatitis in Minnesota. In volume 12, W. A. Riley had a paper on "The Importance of Stained Preparations in the Study of Amebic Infections." In the same volume P. W. Brown published a paper on "The More Common Intestinal Parasites of the Northwest." This subject had been presented from the Mayo Clinic fifteen years or more before this report. R. L. Wilder and F. C. Rodda in this same volume presented an article on "*Diphyllobothrium latum* (Fish Tapeworm) Infestation in Children: Report of Two Cases." In volume 14, R. J. Moe and W. A. Coventry published a paper on "Trichomonas Vaginalis Vaginitis," in which they reported ninety-five cases of their own. They stated that the frequent occurrence of *Trichomonas vaginalis* had activated an interest which had then reached its peak. This organism was discovered by Donné in 1836. In volume 15, E. D. Plass published a paper on "Recent Advances in the Study of the Cause and Treatment of Leukorrhea." *Trichomonas vaginalis* was emphasized as a probable cause. An editorial appeared in volume 16 on "Amebiasis and a Century of Progress." The editor concluded that it seemed evident that amebiasis was not being diagnosed generally. In volume 17, J. N. Gehlen reported a case of amebiasis complicated by abscesses of the liver, lungs and brain. In volume 18, P. W. Brown and T. B. Magath had an article on "Amebiasis: Diagnosis, Prevention and Treatment."

Perhaps the greatest advances in laboratory medicine have been made in the field of blood chemistry. As physiologists and research workers have proved the reliability and diagnostic worth of new procedures in physiologic chemistry, the clinician turns to the clinical chemical laboratory for these aids to routine diagnoses. Much of this work originated about twenty to twenty-five years ago. In 1923, Moses Barron published in Minnesota Medicine a paper that was read in October, 1922, at the state meeting on "The Value and Importance of Blood Chemistry in Clinical Medicine." At this time he especially emphasized the blood sugar test, the urea determination, creatinine determination and uric acid determination. Since that time there have been numerous changes in technique. New methods have been devised for the determination of amino acid nitrogen in blood. Sullivan's work on the determination of cysteine and cystine has become the standard. The methods of determining the concentration of cholesterol and cholesterol esters in the blood are practically the same as those of a quarter of a century ago, although changes have been made in the technique for determinations of phospholipid. New methods have been devised for the determination of blood chlorides and the sugar tolerance test has been partially supplanted by the one-hour, two-dose tolerance test of Exton and Rose, brought out in 1934. There have been recent modifications in the methods of determining calcium, phosphorus and phosphatase. The method for the determination of iron in the blood was developed about fifteen years ago. This method and also the Van Slyke oxygen capacity method have been considered standard methods for the quantitative determination of hemoglobin; however, the most recent method for determination of hemoglobin is the photelometric

method used now for about twelve years. The photelometer also has been used for a number of other chemical determinations and a number of similar photo-electric colorimeters are now in use.

As a test of renal function, the urea clearance test was devised about twenty years ago. Recently considerable attention has been paid to the study of clearance of other substances besides urea, such as inulin and diodrast. Sulfate and sulfate clearances have attracted attention. Determinations of sodium and potassium in the blood and urine have become clinical laboratory procedures. Great interest has been directed toward the quantitative estimation of bile pigment in the blood serum and toward the development of various tests of liver function. The Rosenthal bromsulfalein test and Delprat's rose bengal test came into general use about seventeen or eighteen years ago. The galactose tolerance test has been in use for more than ten years. More recently Quick's hippuric acid test has been developed. The Quick prothrombin time test which is used chiefly as a test for the study of coagulation factors also may be used as a test of liver function after the administration of Vitamin K. The use of sulfanilamide and sulfonamide drugs now has brought about the determination of these substances in the blood and urine as a clinical laboratory procedure. I might mention many more substances for which quantitative determinations must be made in clinical investigation. The research of today becomes the routine of tomorrow in this ever-expanding field of laboratory medicine.

In connection with clinical pathology the vocation of medical technology for well-trained women has developed. Twenty years ago in volume 6, W. E. King presented a paper on "The Training of the Laboratory Technician." In the same volume of Minnesota Medicine, Kano Ikeda presented a paper on "Standardization of Clinical Laboratories and Technicians." In the discussion of this paper R. O. Beard outlined the proposed plan for the University of Minnesota, School of Medical Technology. This was started twenty years ago. In 1923 there were two graduates. From that time through June, 1942, there have been 471 graduates. In volume 17, 1934, of Minnesota Medicine, Ikeda, as secretary of the Board of Registry of Technicians of the American Society of Clinical Pathologists, published an article on "Laboratory Technicians." He stated, "Today it is generally accepted that the particularly technical or mechanical part may be invested wisely in the hands of trained medical assistants, whose duty it shall be to devote their skill and energy in the performance of the various technical methods demanded of the laboratory." The Board of Registry was established fourteen years ago in 1928. Standards for the training have been well laid down by the American Society of Clinical Pathologists and the American Medical Association. A minimum of two years of college work with training in basic sciences plus at least twelve months of intensive training in a hospital laboratory training school is required before the technician is eligible for examination for registration. There are now many thousands of registered technicians and up to the present the supply does not meet the demand. Commercial schools have been set up which pretend to give adequate training; these advertise in lay journals but offer little for the high tuition charged. However, the standard for recognized hospital laboratory training schools has been kept high by the American Society of Clinical Pathologists and the American Medical Association, so that for the most part technicians are really well trained.

Reference has been made to the American Board of Pathology and its definition of clinical pathology as a specialty in medicine. In June, 1935, the Section on Pathology and Physiology of the American Medical Association and the American Society of Clinical Pathologists appointed committees which acted jointly in consideration of the formation of an American Board of Pathology. The Board was organized July 19, 1936. There was an immediate response on the part of pathologists all over the country for certification by this Board as to their qualifications either as specialists in pathologic anatomy or clinical pathology or both. Up to the time of the preparation of the 1942 edition of the *Directory of Medical Specialists,* certified by the various American Boards, more than 800 specialists had been certified by the American Board of Pathology. Since that time more than 150 more candidates have either passed the examination or have applied for examination. Of the number whose names appear in the Directory, 148 are certified in pathologic anatomy alone, ninety-one are certified as clinical pathologists

alone, while 566 are certified in both pathologic anatomy and clinical pathology. In other words, in this 1942 Directory more than 650 specialists are listed who are qualified in the field of clinical pathology. As would be expected, these are distributed according to population. The most populous states of California, Illinois, New York and Pennsylvania have the largest number that are certified. In New York State there are more than 100 qualified clinical pathologists, in Pennsylvania more than seventy, in California about fifty and in Illinois nearly forty. Minnesota has five specialists that are certified in clinical pathology alone and ten in both clinical pathology and pathologic anatomy. Seven men are certified in both clinical pathology and pathological anatomy in the Provinces of Canada, three in Hawaii, three in Puerto Rico, one in the Canal Zone and one in the Philippine Islands.

Minnesota Medicine appeared at a time when the country was making every effort toward winning the World War of 1914-1918, and now at the time of the publication of the Twenty-fifth Anniversary number the medical profession and the entire nation are discussing many of the same problems. It became evident when physicians were called to service that there was a shortage of clinical pathologists both for military service and for the civilian population. While from necessity training in specialties for many recent graduates must be deferred for the time being and while it is not proper nor safe to make too sweeping predictions about the future, it is fair to assume that this specialty will continue to attract young men who are interested in laboratory medicine and scientific methods for diagnosis, and that the next quarter of a century will see proportionately greater strides in all fields of medicine and particularly in the use of the laboratory.

TWENTY-FIVE YEARS OF "MINNESOTA MEDICINE" AND OF ANESTHESIOLOGY

JOHN S. LUNDY, M.D.
Rochester, Minnesota

THE journal, Minnesota Medicine, is twenty-five years old. Within that period, the specialty of anesthesiology has greatly developed. The state of Minnesota has contributed its share in this development and Minnesota Medicine has done its part. I shall emphasize Minnesota contributions but, obviously, it would be impracticable to confine this review to achievements in any one state.

Local and Spinal Anesthesia

From an historical point of view, the late R. E. Farr, of Minneapolis, comes to mind in regard both to Minnesota Medicine and anesthesiology. He was instrumental in bringing Minnesota Medicine into existence and anesthesia, especially local anesthesia, was a primary interest among his many activities. In 1923 he published his textbook on local anesthesia.[3] This had a salutary effect on local anesthesia throughout the country and was a potent factor in arousing interest in the use of local anesthesia.

To begin at the beginning of the story, however, it should be said that, prior to the time of publication of Farr's book, attempts to interest people in local and spinal anesthesia had been made in Minnesota. As early as December, 1909, Thomas Jonnesco[9] anesthetized three patients at the Rochester State Hospital, using spinal anesthesia. In one case amputation of the forearm was performed and Jonnesco wrote, "In this case analgesia was perfect. The patient was conscious and had no ill effects whatever, either during or after the operation." W. C. MacCarty, who saw the demonstration, has said that stovaine was the the agent used. However, it was not until 1920, when C. H. Mayo brought Gaston Labat from Paris to Rochester for a period of ten months, that local, regional, and spinal anesthesia were given real trials in Rochester. Gaston Labat's textbook, "Regional Anesthesia; Its Technique and Clinical Application" (1922)[7] did a great deal toward more general acceptance of regional methods of anesthesia. After Labat's departure, William R. Meeker continued Labat's work for a lit-

From the Section on Anesthesia, The Mayo Clinic, Rochester, Minnesota.

tle more than two years. In the latter part of 1923 the work was carried on by various fellows in surgery of the Mayo Foundation. The one who kept the fires burning was W. H. Sprunt. He was active in this capacity for the first half of 1924 and introduced me to the various procedures then in use in regional and local anesthesia. Interestingly, spinal anesthesia was used in Rochester but once that year and was not used in 1925 or 1926.

Since that time spinal anesthesia has become more and more widely used. Various local anesthetic drugs have been introduced, such as nupercaine, pontocaine and metycaine. The problem had been how to give a safe dose and at the same time produce anesthesia that would last for a long enough period. This problem was finally solved by W. T. Lemmon[8] of Philadelphia, in 1940, when he presented his method of continuous spinal anesthesia. This is a very valuable contribution and demonstrates how a new method can increase the usefulness of an old agent such as procaine. R. A. Hingson, of the United States Public Health Service, had training in anesthesia in the Mayo Foundation in Rochester, in 1940-1941. In 1941, shortly after he left Minnesota, he developed, in conjunction with W. B. Edwards,[2] a method of continuous caudal anesthesia in obstetrics. This method is full of promise, as it can be used for labor as well as for delivery. It demonstrates the different origins of the sensory and motor innervation of the uterus and is the newest method in anesthesia at the present time.

Anesthesia by Inhalation

Some pioneer work in inhalation anesthesia was done in Minnesota. For example, the open drop method of administering ether was brought to a high state of development in Rochester by nurse anesthetists[15] under the supervision of A. W. Stinchfield and Isabella Herb.

Chloroform has not been in favor in institutional practice in Minnesota during the last twenty-five years. However, it has been used to some extent in rural practice, especially for obstetrics. Administration of chloroform occasionally is associated with sudden cardiac failure; in some cases there is delayed central necrosis of hepatic lobules, with fatal issue. From time to time it has been suggested that this drug be administered with oxygen in order to avoid the hepatic damage. This technique has not been perfected, however, although some day it may be. It is said that sulfanilamide, as well as xanthine, prevents hepatic damage from chloroform. I have not used chloroform since 1927.

The story of gas anesthesia in Minnesota begins at least as early as 1900, in so far as surgical cases are concerned. It was first used in Rochester on November 25, 1900, and in a few cases that month and the next. It was not used again in Rochester until October, 1918, when the dental surgeon, Boyd S. Gardner, employed nitrous oxide and oxygen for dental extraction. It has been in continuous use in Rochester since that time. In Minneapolis, J. A. Heidbrink had been using gas anesthesia for some time. In 1910 he developed the technique of "timed anesthesia," in which nitrous oxide and oxygen, instead of nitrous oxide and somnoform were used. He used reducing valves as flow meters. In the following years, in association with B. J. Clark, Heidbrink developed the gas machine that bears his name. The machine was for use not only in dental surgery but in general surgery, and Heidbrink's machine and technique became used throughout the world. About this same time, Connell, McKesson, Forregger and others began the manufacture of gas machines. In 1918, Luckhardt and Thompson were experimenting with ethylene as an anesthetic agent and it came into clinical use in March, 1923. It was brought to Minnesota and used in Rochester in May, 1923.

In 1925, Ralph M. Waters introduced the soda lime absorption method of gas anesthesia; a method which made possible clinical introduction of the gas, cyclopropane, by Waters, Neff and Rovenstine in 1933. This was a great advance in gas anesthesia and there has been no marked advance along that line since that time except for the work of Woodbridge and Tovell in studying measures to minimize the explosive hazard of anesthetic mixtures.

Divinyl ether was suggested by C. D. Leake,[6] now of Texas, in 1930 and was recommended for clinical use by Goldschmidt, Ravdin, and associates,[4] in 1933. Divinyl ether has proved to be a useful anesthetic agent for short, minor operations.

Rectal Anesthesia

Rectal anesthesia was developed in a practical way by Gwathmey, in 1913, and in his book,

"Anesthesia," published in 1914, considerable space was devoted to the use of ether and oil by rectum. The method became well known and was used extensively, especially in obstetrics, until tribromethyl alcohol was introduced and became generally accepted in 1926. The rectal method of anesthesia is accepted less as the sole method of anesthesia than as a means of production of basal narcosis, to be supplemented by other methods such as local, inhalation, or intravenous anesthesia. However, it is useful in certain situations; especially when a patient has to be treated in a dark room under roentgenoscopic control. The development of rectal anesthesia took place very largely in the last twenty-five years.

Intravenous Anesthesia

Intravenous anesthesia, which was first used by Ore, of France, in 1872, when he injected chloral hydrate intravenously, did not become widely used for many years, although a number of agents were tried. The story of this development will appear in R. C. Adams' forthcoming book on intravenous anesthesia. It was not until 1929, when Zerfas[14] reported on the use of sodium amytal, given intravenously, that the modern trend toward the use of intravenous anesthesia developed. I made one of the early reports on the use of sodium amytal in Minnesota, in 1930,[10] and the following year I made a report on the use of sodium nembutal (pentobarbital sodium)[11] as an anesthetic agent for intravenous use. These drugs were not satisfactory; therefore, the method did not become generally accepted. In 1932, Weese and Scharpff[18] introduced evipan, now called evipal, and great interest was aroused in the intravenous method. In 1935 I reported the use of pentothal sodium for intravenous anesthesia[12] and, since that time the method has become widely adopted because the agent has been relatively satisfactory; however, in further investigations better agents may be developed.

Endotracheal Anesthesia

One of the great advances in anesthesia was made by I. W. Magill, of England, in 1920, when he modernized endotracheal anesthesia. In 1928, in Winnipeg, at a joint meeting of the British and Canadian Medical Societies, he read a paper on endotracheal anesthesia and presented an intratracheal tube of large bore and made of relatively soft rubber. He visited me in Rochester and left with me his equipment, including laryngoscope, connectors and tubes. I persuaded the Heidbrink Company of Minneapolis to manufacture the Magill rubber intratracheal tubes. Of course, competitors followed their example and shortly the tubes were generally available and were widely used, to the great advantage of patients, surgeons and anesthetists. The endotracheal method is one of the most valuable techniques in all of anesthesia.

Research

The foregoing is evidence that clinical anesthesia has made much progress in the last twenty-five years. A good deal of research also has been carried on in this field, not only in laboratories of chemistry but also in laboratories of physiology, pharmacology and anatomy. Unfortunately it cannot be assumed that the human being will react exactly as the laboratory animal does to various agents and methods. Still, in general the effects are similar and progress in clinical anesthesia is in a large part dependent on further knowledge obtained from laboratory experiments. This is true also in fields allied to anesthesia, which have come to be included in the field of anesthesiology. Oxygen therapy, transfusion of blood,[16,17] treatment of shock and use of supportive measures, including administration of stimulants, have seen their greatest development in the last twenty-five years. The extensive use of refrigeration has made possible so-called blood banks. The development of processes for drying plasma and for solidly freezing it have added to the scope of use of this material; thus medical practice has been improved, many lives have been saved and plasma will be of the greatest value in the present war.

Publications, Organizations and Minnesota's Educational Efforts

From the standpoint of publications and development of organizations of anesthetists, most such progress has occurred in the last twenty-five years. In 1920, Crile and Lower[1] published their book on anesthesia. Labat's book has been previously mentioned. Publication of the magazine, *Current Researches in Anesthesia and Analgesia,* began in 1922. In the same year, in England, occurred the first meeting of the Section on Anes-

thesia of the British Medical Association. In 1923, the *British Journal of Anesthesia* was issued for the first time. In 1927, the first meeting of the Section on Anesthesia of the Canadian Medical Association was held. In Germany, in 1928, was begun the publication of *Narkose und Anæsthesie* and, in 1929, the publication *Schmerz* was united with the former. The year 1933 saw the first publication of the *Bulletin of the National Association of Nurse Anesthetists.* In Italy in 1935, the *Giornale Italiano di Anestesia e di Analgesia* was first published, and the same year, in France, saw inauguration of the new journal *Anesthésie et Analgésie.* In 1937, the American Board of Anesthesiology, Incorporated, was formed. In the same year Guedel published his book "Inhalation Anesthesia." It was also in 1937 that, in Minnesota, "Anesthesia Abstracts" first appeared. In 1938, Beecher published his "Physiology of Anesthesia." In Argentina, in 1939, publication of the journal *Revista Argentina de Anestesia y Analgesia* was begun. Publication of the journal, *Anesthesiology,* was started in 1940 and, in the following year, the first meeting of the Section on Anesthesiology of the American Medical Association was held. "Fundamentals of Anesthesia" was prepared by the Subcommittee on Anesthesia of the National Research Council and was published by the American Medical Association in 1941. "Endotracheal Anesthesia" by Noel A. Gillespie was published in 1941 and "Clinical Anesthesia," a book written by myself,[13] was published in 1942.

In education, Minnesota has taken a leading position. Since 1920, Ralph T. Knight has been in charge of anesthesia at the University of Minnesota and he has taught, and stimulated interest in the subject in the medical school of the university. He has organized the practice of anesthesia in the University of Minnesota Hospitals and in the Minneapolis General Hospital. He acts as a consultant in anesthesia to other hospitals in the Twin Cities. He has stimulated the interest of many individuals in anesthesia and has contributed to the progress of the specialty in many ways. In March, 1923, the University of Minnesota established a fellowship in anesthesia leading to the degree of Master of Science in Anesthesiology. The first person to receive this degree was E. B. Tuohy (1936). Since that time ten have received the degree.

The Immediate Future and the Anesthesiologist's Debt to "Minnesota Medicine"

In the present war, the armed forces are making every effort to train and employ as many physician anesthetists as possible. This will increase the ranks of anesthetists considerably and it would be reasonable to suppose that, after the war is over, and those men return to civilian practice, the specialty of anesthesia will receive the same impetus that thoracic surgery received after the war of 1914-1918. With respect to its past progress and future prospects, the specialty of anesthesia owes a debt of gratitude to MINNESOTA MEDICINE for the many papers on anesthesia and allied subjects which it has published. I can fittingly close this necessarily incomplete review by wishing for MINNESOTA MEDICINE a long and successful existence. This I believe to be the desire of all Minnesota physicians and many others elsewhere.

ABDOMINAL PAIN

ARNOLD SCHWYZER, M.D.
Saint Paul, Minnesota

OUR understanding of the pathways of the conduction of abdominal pain has been cleared up only during more recent years. That the parietal peritoneum is very sensitive was well known, but what about the intra-abdominal organs? In 1898 Jaboulay made the attempt to relieve pelvic pain by attacking the sacral sympathetic chain through an approach from behind the rectum. This did not bring distinct results. Fontaine and Hermann of Strasbourg (1932) gave a good historic picture of the development of the surgical measures on the pelvic sympathetic nerves in gynecology where they mention that Ruggi, about a year after Jaboulay, published his "work on abdominal sympathectomy in functional disturbances of the female genital organs." He advised the resection of the utero-ovarian plexus by the transperitoneal route. For a long time gynecologists had examined closely the distributions of the pelvic sympathetic nerves. Lee of England (1849) and Frankenhaeuser of Zurich (1867) had studied the nerves of the uterus.

Then came Lennander, the surgeon of Upsala, in 1906 with his epoch-making observations on the perception of pain in the abdominal organs. Though we now know that they are but partially correct, his findings stimulated the study of this subject. He told us that all of the organs which were only supplied by the sympathetic or the vagus below the branching off of the recurrent laryngeal nerve had none of the four kinds of sensation, namely pain, pressure, heat and cold perception. This he demonstrated convincingly concerning bone substance, bone marrow, cartilage, thyroid, lung, stomach, intestine, mesenteries, omentum, gall bladder, liver, pancreas, spleen, the serosa of the urinary bladder, also the kidney parenchyma after the renal fat is completely removed from the fibrous capsule. On the other hand he found perception of pain on the periosteum, the joint capsules, the parietal pleura and the parietal peritoneum. Concerning these two large body cavities, pleura and peritoneum, he stated that what hurt most was a displacement of their delicate lining membranes over the underlying tissues. The nerves which run in the subserosa and which are irritated by pulling on them are of somatic origin, branches of the intercostal, lumbar, and sacral nerves. Lennander's positive observations were of greatest practical importance for the abdominal surgeon who in those days liked to operate where possible under local anesthesia. Lennander did not know of the pain-conducting fibres in the sympathetic, which gynecologists had recognized. The important thing which resulted from Lennander's research is the fact that apart from the pelvic organs and perhaps some portions of the splanchnic nerve along the deeper biliary channels his observations hold good in most of the work which the surgeon is called upon to do in the abdomen.

Mackenzie and Head made valuable contributions in developing the conception of so-called segmental referred pain. Mackenzie's law states that "when a painful stimulus is applied to a part of low sensibility in close central connection with a part of much greater sensibility, the pain produced is felt in the part of high sensibility rather than in the part of lower sensibility to which the stimulus was actually applied." As I understand these authors, visceral and somatic receptor centers are closely associated and through a visceral stimulus an irritated state occurs in this central area which causes a lowered threshold of sensation. As a consequence normal painless stimuli from the body surface which are always present are felt as pain, which is referred to the corresponding surface district.

So much for a short orientation in referred pain. This paper is written from the standpoint of the practitioner as a clinical talk. Operating under local anesthesia has allowed us to verify Lennander's statements time and again. Their value lies in the observation that large areas have no sensation. When an abdominal operation is done under local anesthesia it is most important to avoid pulling on the intestines as the posterior mesenteric attachment is keenly sensitive. The segmental referred pain transmitted through the autonomic system plays a minor role *in praxi* compared with local tenderness which travels through somatic channels. Referred pain may

mislead the surgeon if he is not constantly aware of its possible abnormal localization. The pain may be very severe. It is seldom as definite and circumscribed as local tenderness due to a localized inflammatory condition. However, it may at times simulate even such a condition.

For example last winter I had a patient who had suffered for years from headaches and a vague abdominal distress. She then developed a marked local tenderness under the *left* border of the ribs. She was thoroughly discouraged and when one pressed under the left border of ribs she winced with pain while she did not complain when the same pressure was applied on the right side. X-ray examination of stomach, colon, and also for possible diaphragmatic hernia, gave normal findings. The gall bladder, too, functioned normally on roentgenologic study. The history was quite vague. The patient was generally run down and despondent on account of carcinophobia; but she was not of the common complaining kind. The proposal to open and examine was gladly accepted by the patient, a fact which confirmed our impression that there must be some definite pathologic process behind all this. At operation the stomach and all the left-sided organs were found to be normal. The gall bladder, which we had under suspicion, having made an x-ray examination some time before, was white but did not show any further changes like adhesions, nor was there a fibrous network in the overlying liver tissue commonly found in chronic infection of the gall bladder. There were no stones. Hesitatingly we removed it and also a long somewhat club-shaped appendix. On opening the gall bladder it proved to be of the strawberry type. Eight days after the operation the notes read that she felt very well, was up and about since two days after the operation, and had no complaint. The daily headache from which she had suffered for fifteen years had gone since the operation and also the left-sided pain. None of these symptoms has troubled her from then on. Here we had a misleading localization of a referred pain on the opposite side.

In judging the subjective localization of pain we must also consider the following. The newborn baby does not have the ability to locate pain from the start. It has to learn first from which area a certain pain comes. This pain is then projected to the corresponding surface. Gustatory sensations (like all others) are formed in the brain, but projected to the mouth. Visual and auditory sensations are projected to locations outside of us at some distance. The baby learns this gradually by way of control and comparison. But we have very little or no experience with an exact localization of pain in the abdomen apart from the parietal peritoneum. Our ability to localize a pain inside is simply not developed. *In praxi* I find that surprisingly often the patient localizes his pain wrongly as to the affected side.

It is apparently proven experimentally, but not really understandable, that abnormal distention or contraction of a viscus can cause pain though the surgeons have proved that other painful manipulations as pinching, cutting, or burning are painless if pulling is avoided. After having observed this in hundreds of laparotomies under local anesthesia I cannot bring myself to accept the conclusions drawn from these experiments. Balloons were placed into the gall bladder and again into the duodenum and then distended. There must always occur a displacement or pulling to some extent on the neighboring posterior peritoneum which is extremely sensitive. This may explain the findings in experimental work. Pulling on the gall bladder is painful, but crushing or cutting it is not. An abnormally firm contraction will have a pulling quota on the adjoining posterior peritoneum, the same as distention.

An inflamed intestine or appendix does not hurt when pinched at operation unless we pull on these organs. Then the pain is severe because the posterior peritoneum is exquisitely sensitive to any degree of traction. And this is of course much worse when the posterior attachment is irritated by a continuation of the inflammation of the viscus. The most delicate handling of the intestines and particularly avoidance of any pulling is necessary to operate painlessly. Severe crampy contraction of part of the stomach wall where it is grasped by a probang during an operation is not felt in the least. The whole circumference of the small or large intestine can be caught in a crushing clamp and if we avoid pulling on the mesentery there is no sensation. There is no sensation even if a short loop of small intestine is in such firm contraction as to form a solid cord which one can see at times when operating under local anesthesia.

The large intestine cannot contract forcibly in its ascending and descending portions without a

pulling effect on the meso-colon which is very short. Thus severe contraction can well cause pain through the lateral attachment of the colon. But how about over-distention, which in experiments seemed to cause pain? If a long ileum loop is overdistended it straightens out more or less and becomes rigid, which will cause a pulling on the fan-shaped mesentery. This will not happen so readily in the small intestine as in the large one with its greater fixation. Thus the crampy pains in common minor disturbances as diarrhea have their origin practically always in the colon.

Head's and Mackenzie's findings often give valuable hints. For instance, a pain between the shoulder blades leads our attention immediately to possible gall-bladder trouble or a deep-seated ulcer. In the uppermost part of the abdomen several organs, if inflamed, will affect the same center of cutaneous sensation. The patient has no way of recognizing directly what organ causes the pain in this area. On the other hand localized tenderness, when present, is of course of particular value for a differential diagnosis.

An appendicitis patient, a man, was so emphatic that his pain was directly underneath the ensiform process and he was so incredulous as to my diagnosis that I was anxious to demonstrate to him that local tenderness over the appendix meant more than his spontaneous epigastric pain. I operated under local anesthesia. The reddened appendix rested against the posterior peritoneum. When I grasped it with an artery forceps there was no pain but when I pulled on it the patient suddenly reacted and told us emphatically with groans that he had again that old pain in the pit of the stomach but assured us that he felt absolutely no pain where we were operating. I said "if you count up to three your pain is gone." Though very evidently unconvinced he counted in a hurry, whereupon I released the tension without removing the forceps from the appendix. With a puzzled laugh he admitted the pain was gone. The pain of pulling must have been severe as he could not be induced to have the experiment repeated. We then infiltrated the mesenteries of the appendix and adjoining cecum which caused the remainder of the operation to be painless.

To corroborate the statement that even in severe inflammation the appendix and the walls of adjoining intestines have no sensation for pain let me tell you of the following case: A woman came to my office complaining of a "dysentery" from which she had suffered for a number of days. She looked quite sick, felt miserable and had fever between 101 and 102 degrees. She complained, however, of no particular or outspoken pain. In the right iliac region there was a movable mass the size of a woman's fist. It was not tender in itself and caused only moderate discomfort on being moved about gently. Operation revealed a gangrenous appendix in an abscess which was walled off entirely by the cecum, adjoining ileum and omentum. The cecum was of the "cecum mobile" type. There was no involvement of the anterior or lateral peritoneum and there was a rather long stretch of mesentery between the inflamed gut and the posterior peritoneum.

It should be mentioned that in appendicitis we almost always find a pain at McBurney's point even if the cecum is far down in the pelvis. This is due to the fact that the lymphatics from the appendix reach the posterior abdominal wall at this point even if the cecum and the appendix are low down in the pelvis. Infected lymphatics involve promptly the adjoining tissues as one well knows from the red streaks in lymphangitis of the arm or leg. This causes the peritoneum at McBurney's point to become very tender to pressure.

Concerning appendicitis Rovsing called attention to the following symptom. On pressing into the left iliac fossa a pain is at times felt on the right side. Rovsing thought this might be due to gas being forced from the left side of the colon over to the right. However, if we consider the long stretch of colon with its flexures that the gas would have to traverse, it is evident that this cannot well be the case. The explanation most reasonable is that we displace the intestines and create some pulling on the inflamed posterior peritoneum in the neighborhood of the appendix. When an inflammatory condition is suspected and gentle pressure causes no indication of pain, sudden release may be painful. This pain on rebound is proof that the primary palpation was properly gentle and it indicates a local irritation of the posterior peritoneum.

At times pain is felt far away from the place of trouble. Thus in a case of traumatic rupture of the diaphragm in its right parasternal portion, there was a pain in the right iliac region where

there was, however, no tenderness. The radiograph showed a loop of colon in the pleural cavity reaching as far as the upper level of the heart. This pain may have been a referred pain or was caused by traction.

The center of the diaphragm is known to yield only referred pain in the neck. However, the peripheral portions of the diaphragm yield local pain. In a case of long standing fever with a history of dysentery contracted in the South, a tenderness on pressing upward underneath the border of ribs led us to recognize a liver abscess which was ready to break through on the upper surface of the liver. It was the irritation of the peripheral diaphragmatic peritoneum which gave the information.

Though I have been able to observe many times during operations that the liver has no trace of sensitiveness, very large livers cause a vague "misery" partly from pressure, but, besides this, the weight and size may produce a pulling on the different fixatory ligaments.

The most important epigastric lesions are perforated ulcer, gallstone attack, and acute pancreatitis. Their differentiation especially in reference to the character of the pain may be discussed in short. In acute perforated ulcer, pain is overwhelming and the patient does not dare to move. He lies very quiet because the pain is peritonitic and every movement increases it greatly. On the other hand in an attack of gallstone colic the excruciating pain makes the patient throw himself around, and he often cannot even stay in bed, but gets up and doubles over. In pancreatic apoplexy or peracute pancreatitis the picture is again different. The pain is steady and severe, but not as excessive as in the two just mentioned conditions (perforated ulcer and gallstone attack). Because the anterior parietal peritoneum is not involved, the local tenderness is therefore not as severe as in perforated ulcer. The abdominal muscles are contracted but not as board-like as in perforated ulcer.* In pancreatitis the trouble is located primarily in the lesser peritoneal cavity. A leakage through the foramen of Winslow will only occur, if at all, at a later stage. There is a steady great pain due to the irritation of the posterior parietal peritoneum, but surface displacement which is the most sensitive of all does not occur here to any great extent. The involvement of the large sympathetic tracts and solar plexus brings about the outstanding feature in this condition, which is a sensation of impending death. The pulse, which is bounding for hours after perforation of an ulcer, is very feeble and thready in acute pancreatic disease.

The gall bladder apart from gallstone colics can be the seat of a steady pain in acute inflammation. The local pain and tenderness are clear-cut and well localized, due to involvement of the anterior or posterior parietal peritoneum or the lymphatics in the latter.

Pain, even quite localized, over the gall bladder occurs in coronary disease and one may find it so sharp on pressure, that the thought of a concomitant cholecystitis is often aroused. Ravdin and Royster have shown very recently that "many of the classical signs of angina pectoris" are seen in gallstone cases and are cured by operative measures. The distinction from true angina lies in the observation that the symptoms are not elicited by physical effort. They call the condition pseudo-angina.

Other serious errors occur at times. I remember on one occasion being consulted in a case which a colleague thought to be an acute cholecystitis for which he was ready to operate. I advised him to wait with any further measures until the lobar pneumonia which had escaped him was over. The pneumonia over, the pain was gone.

Of pain due to renal affection it can only be mentioned that at times the localization is poor or even very misleading. Cases of calculi are reported where the pain was located in the sound kidney of the opposite side. In the case of a recent descent of a stone in the ureter the pain usually is excruciating and radiates toward the bladder or testis. Let me tell you of the case of a very experienced surgeon. During an operation he was caught with an overwhelming pain in his own abdomen. Morphine helped little. When I saw him the pain was still severe and the whole abdomen of this large sized man was ballooned and hard. The patient thought the right iliac was more tender than the rest and in case it was an appendicitis no time was to be lost. He wanted to have this matter settled by exploration. Like the rest of the intestines the

*In the November meeting of the Minnesota Academy of Medicine, Dr. R. T. LaVake mentioned a case of acutely perforated ulcer right after childbirth. The abdomen was not at all hard and therefore the picture was very misleading. The overstretched abdominal muscles had not yet become shortened enough to allow the abdominal walls to become firmly contracted.

appendix was somewhat congested. It was removed, though we well saw that it did not account for the acute symptoms. Some time later this man passed a ureteral calculus from what he felt sure was the *left* side.

The ureter is normally devoid of sensation, but the excruciating pain when a calculus becomes stuck in it is only too well known. The nerve supply of the ureter proper comes entirely from the autonomis system. Though, according to J. C. White, the ureter itself is said to have afferent nerves, one may well look for the least part of painful sensation in its very close connection with the peritoneum. It is well known to the surgeon who has to attack the ureter and looks for it by the extraperitoneal route, that when he lifts the peritoneum off from the underlying structures in the iliac fossa he always finds the ureter on the peritoneal side of the wound on account of the marked degree of attachment between ureter and peritoneum. In case of abnormally severe contraction of the ureter the overlying peritoneum is pulled on and such displacement is particularly painful. How far such an explanation of the pain in ureteral colic holds good is hard to decide. Stripping and freeing the ureter has brought about relief in cases of ureteral pain and colic, but was it not due to the separation from the closely adherent peritoneum? In catheterizing the ureter, pain is first felt by the patient on entering it as a bladder sensation. From then on there is no pain or sensation unless the catheter is inserted too far and impinges on the upper calix in the renal pelvis. The kidney pelvis has sensation, though the kidney parenchyma has none.

The microscope has shown that the nerve fibres of the autonomic system have no myelin sheath or at most a doubtful indication of such in the form of a faint stippling surrounding the fibres. A well developed myelin sheath is considered to be the attribute of somatic nerves. However, it has been observed that in the superior pelvic plexus about one-third of the fibres are sheathed with myelin. In the paravertebral sympathetic chain also have been found large myelinated neurones. This would mean that somatic sensory fibres run along in the track of nerves which are classed as belonging to the autonomic system. Indeed, this microscopic investigation followed the clinical observation of surgical relief from certain pelvic illnesses as uncontrollable dysmenorrhea. The superior pelvic plexus, also called the presacral nerve, can be dissected out from between the shanks of the bifurcating aorta downward and this has given surprisingly good results in different pelvic troubles. My experience is limited to five cases, in all of which satisfactory results were obtained. In one instance it was not much more than an experiment, inasmuch as I had not read of such procedure for the condition with which we were confronted. On that account I will describe the case in short, though it really lies outside the subject of "abdominal pain." A woman, about fifty-five years old, was suffering from a pruritus vulvae which made her act like a maniac and drove the whole family to despair. With a distorted face she moved about excitedly and incessantly. Then at intervals she would suddenly stop and scratch herself violently amid groans. She had had local and general treatment by other doctors. Local injections by us were of no avail. As a last attempt we resected the superior pelvic plexus with not only immediate but perplexingly complete relief. There has been no sign of any return of the trouble since the operation which was done about six years ago.

Results with resection of the presacral nerve stimulated closer investigation. Learmont's studies made in common with Braasch are outstanding in this field. They observed that a crushing pain in the bladder was complained of on grasping the nerve. Learmont states that these afferent neurones run with the sympathetic nerve tracts and reach the spinal cord between the ninth dorsal and the fourth lumbar segments. These fibres conduct pain, but the mentioned authors found that after resection of the presacral nerve the sense of touch or pain in the bladder is not abolished but instead remains good on intravesical manipulation. Indeed, the relief from the bladder pain after resection of the presacral nerve was not complete. Though it is often difficult to be sure that all the fibres of the presacral nerve have been divided because it varies greatly in the distribution of fine lateral threads, Learmont came to the conclusion that much of the sensation, especially of the lower portions of the bladder, runs with the parasympathetic tracts which join the sacral nerves.

In summing up the observations on abdominal pain, emphasis must be given Lennander's findings that the parietal peritoneum is by far the

most sensitive structure in the abdomen and as it is supplied with somatic nerves, it gives us the most direct and most helpful information. Besides this there are myelinated sensory fibres running along autonomic tracts, though (because they are myelinated) they are considered as belonging to the somatic system. In addition there are apparently afferent fibres in the sympathetic network which report trouble to the nearest sensory centers. Their messages, though often quite loud, are much less clear and definite than those of the somatic system.

EVOLUTION OF NEUROSURGERY

ALFRED W. ADSON, M.D.
Rochester, Minnesota

DURING the past twenty-five years I have had the privilege of observing and participating in the evolution of neurosurgery. The outstanding achievements in this period have been: (1) more accurate localization of lesions of the brain and spinal cord, (2) pathologic knowledge concerning the life cycle of neoplasms and inflammatory lesions of the central nervous system, and (3) the refinement of surgical methods dealing with lesions of the central nervous system, such as (a) selecting the proper anesthetics for the various procedures, (b) perfecting asepsis, (c) more accurately controlling bleeding, (d) simplifying craniotomy and laminectomy, (e) developing a better knowledge of intracranial pressure with control of surgical shock, and (f) developing surgical procedures in the treatment of lesions now included in the scope of neurosurgery.

The improvements in the localization of lesions involving the brain and the spinal cord have been due to many factors. The anatomic and physiologic knowledge of the central nervous system has been increased tremendously. Clinicians with the aid of the pathologist have come to understand, evaluate and distinguish lesions, thus selecting lesions that lend themselves to surgical treatment. The use of air or oxygen in studies of the ventricular system and the subarachnoid spaces has contributed much in the further localization of neoplasms. These studies are referred to as pneumo-encephalographic, ventriculographic and myelographic studies. Malformations of normal ventricles and subarachnoid spaces do not only indicate the position of the lesion but also are of value in determining the accessibility and the operability of neoplasms and abscesses.

Electro-encephalography is one of the newer diagnostic procedures employed in the differential diagnosis of cerebral lesions. It is of great value in distinguishing functional disorders from the organic disorders. This is especially true in the epileptic group. It is of moderate value in localizing neoplasms in the absence of increased intracranial pressure. As yet, the findings are too uncertain to be of surgical value in the presence of markedly increased intracranial pressure. The electro-encephalographic findings are also uncertain as a differential aid when the patient presents symptoms that might be attributed to a neoplasm, cerebral thrombosis, or a subdural hematoma. It is very possible that electro-encephalography will prove of greater value in the localization and the differential diagnosis of cerebral lesions as knowledge of abnormal brain waves increases.

The ophthalmologist plays no small part in the localization of cerebral neoplasms. The presence or absence of papilledema and other changes of the fundus with the numerous types of defects of the perimetric field contribute inestimable knowledge in the localization of cerebral lesions. The radiologist likewise contributes a large share in the differential diagnosis. The roentgenogram not only reveals the presence or absence of increased intracranial pressure but also reveals localized erosion and hyperostosis of the skull and vertebræ, which often assists in the localization and in the definition of the character of the lesion as well.

In the beginning of the specialty, some fifty years ago, little was known about the nature and the life cycle of cerebral neoplasms. Too often they were looked upon as inoperable lesions and all classed as gliomas. During these past twenty-

From the Section on Neurosurgery, The Mayo Clinic.

five years the pathologists have not only distinguished the various tumors, but they have also shown that the gliomas differ in character and rate of growth. Although many are rapid in their growth, others grow slowly. In order to illustrate this point, I wish to include the following four paragraphs prepared by our neuropathologist, Dr. James W. Kernohan, of the Mayo Clinic:

The contributions by neuropathologists or others working in the laboratories were almost wholly in the field of histology and were made possible by use of refinements in histologic technique and newer staining methods. Originally, all tumors of the nervous system were grouped together, but the encapsulated tumors were the earliest ones to be separated. These tumors were outside the substance of the brain and spinal cord and were recognized to be of two types; the first arose from nerve roots of the spinal cord and the eighth cranial nerve, and were called neurofibromas and later perineural fibroblastomas. The other group arose from the meninges and were referred to as dural endotheliomas. Mallory pointed out that the dura had no endothelium and that these tumors were meningeal fibroblastomas. However, there was some question as to their origin from the arachnoid cells, and Cushing adroitly avoided this controversy by calling them meningiomas. Later years have led to various subdivisions of these meningeal tumors by Bailey and Bucy, Globus, and still later, Cushing and Eisenhart.

Tumors of the pituitary body also were subdivided into the three types representing the three types of cells in the normal pituitary body, namely, chromophobe, eosinophil and basophil tumors. Being of epithelial origin and being, as a rule, slowly growing neoplasms, they have been called adenomas rather than carcinomas. Each produces a characteristic syndrome; however, the chromophobe adenomas are the ones most commonly requiring surgical intervention for relief of visual disturbances, Eosinophil adenomas produce the most characteristic syndrome of acromegaly, while basophil adenomas do not, as a rule, call for surgical intervention. Of the tumors in the neighborhood of the pituitary body, the most common type is the craniopharyngioma, although it has at times been called adamantinoma, supracellar cyst, Rathke pouch cyst, and so forth. This tumor is most commonly seen in young adults, and since it usually contains calcium salts, it can frequently be visualized and diagnosed by roentgenography.

Many attempts had been made to subdivide the most common tumors of the brain, namely, the gliomas. It remained for Bailey and Cushing, in 1926, to subdivide this interesting group of tumors in a practical and useful manner. They based their work, to a considerable extent, on the excellent metallic impregnation methods of Cajal and his pupil, Del Rio Hortega. It also required a large number of tumors obtained at surgical operations for histologic study, which they correlated with carefully taken clinical histories. This excellent contribution by Bailey and Cushing has remained the basis of all such studies since that time. Only very minor changes have been suggested, and some of these are perhaps unnecessary, being only refinements of the original contribution. This advance by Bailey and Cushing has been of great help to neurosurgeons since it allows them to vary the methods of surgical treatment, whether they employ radical procedures in the relatively benign, slowly growing types, with hope of prolonged, if not permanent cure, or a limited procedure in the highly malignant gliomas with rather hopeless prognosis. This subdividing of the gliomas has been the greatest single contribution which neuropathologists have made in aiding neurosurgeons.

There have been many other contributions of lesser or minor importance by which neuropathologists have aided in the advances made by neurosurgery, but it does not seem justifiable to enumerate them here.

Historical

Cranial surgery[2] dates back to the ancient Egyptians, Romans, and Peruvians, who trepanned skulls to give egress to the evil spirits within, but who also must have treated injuries of the skull if explanation is to be made of the extensive defects present in the skulls preserved in museums. Traumatic cranial surgery undoubtedly was practiced during the various epochs before modern antiseptic and aseptic surgery were introduced. Records show this was true during the Napoleonic wars. The depth of the surgical procedures was limited by the dura, as those who penetrated below the dura met with failures resulting from suppuration.

Richmond Godlee,[4] of London, is accredited with being the first successfully to remove a tumor of the brain. The tumor had been localized by Bennett, who employed the newer neurologic methods. Godlee was able to accomplish the removal by employing Lister's antiseptic technique. The date of this operation was November 25, 1884, and the results of the procedure were reported in 1885. Ballance, in his monograph, "A Glimpse into the History of Surgery of the Brain,"[3] stated that Heyman, in 1931, had removed a tumor of the parietal bone from a patient, eight years of age, who had jacksonian convulsions. Other similar references are found in literature, but the reports differ from that of Godlee in that localized cranial signs, such as presentation of the tumor through the bone, led to the localization, rather than the neurologic symptoms which Bennett observed in localization of the growth. MacEwen, as early as 1876, had

diagnosed an abscess of the frontal lobe because of the contralateral hemiplegia and proposed operation which had been refused by the parents of the patient. Subsequently, the patient died, and MacEwen carried out the steps of his proposed operation at necropsy, and found the abscess. He too had operated on several tumors of the brain using lesions of the skull as localizing signs, before Godlee had operated in his famous case. However, MacEwen's report of abscess entitles him to be called the father[10] of modern neurologic surgery. In the discussion of Godlee's paper, Ferrier reported a case in which tumor of the brain had been localized neurologically; Lister had trepanned but had failed to expose the tumor, but he did so eight days later at necropsy, when he found the tumor in the region explored. At the reading of Godlee's paper, Horsley also was present, and because of his interest in neurology and in the restriction of a surgical field to that of the central nervous system, it has made him the outstanding leader in the pioneer development of neurosurgery.

Weir, of Philadelphia, is accredited with being the first surgeon in the United States successfully to have removed a brain tumor. This operation was performed November 17, 1887, and was reported in 1888. In 1891, Keen reported five cases in which cerebral operations were performed. In the same year, C. H. Mayo[11,12] reported two cases, the first of successful drainage of a brain abscess, and the second of ligation of a common carotid artery for an arteriovenous fistula in the cavernous sinus, with a successful result. Knapp, of Boston, in 1891 collected from the literature and reported forty-six cases in which operation had been performed in the preceding six years and stated that thirty patients had survived the operation, fifteen had died, and the fate of one had not been reported.

Keen, in 1895, commented on the fact that in spite of the rapid progress and brilliant achievement of modern antiseptic surgery, cerebral surgery had made but little advance until 1886, when Horsley and MacEwen introduced radical changes in surgical technique. He stressed the importance of disinfection and urged that the head be shaved a day before the operation, that it be well scrubbed with soap and water before applying ether and the 1:2,000 sublimate solution. He emphasized the importance of the precept that the surgeon's arms, hands and fingernails be thoroughly cleansed, and that the instruments and dressings be scrupulously clean. He referred to the Wagener-Wolfe osteoplastic flap, but advocated removal of the bone overlying a tumor by cutting the bone between the trephine openings. He closed the skin flap without replacing the bone until a secondary operation. The dura was closed with sutures of catgut and the skin with interrupted sutures of silkworm gut. The wound was covered with ample sterilized dressings which were kept in place by wet bandages covered by muslin bandages. In 1896, Keen presented another paper entitled "The Surgical Treatment of Intracranial Tumors," in which he reviewed the status of surgery of the brain. He complained of ineffective methods of localization of cerebral tumors and emphasized the importance of having the coöperation of a neurologist and an ophthalmologist in consultation. He believed that the roentgen rays, which had come into moderate use, should offer aid. In reviewing the various types of craniotomy, he stated that the Wagener-Wolfe method consisted of exploration by raising an osteoplastic flap over a circumscribed area. Horsley, in employing the osteoplastic flap, cut the bone between the four trephine openings with a straight saw. Krause changed this technique by employing a motor-driven circular saw, and Cryer employed a motor-driven circular osteotome in cutting the margins of the bone flap. Doyen advocated a more radical procedure, in that his osteoplastic flap amounted to hemicraniotomy. Keen said that if the tumor were small, the operation should be completed in one stage, but if it were large, it would be better to divide the operation into two stages. He advocated that Horsley's bone wax be used for the control of venous bleeding along the cut margins of the skull, that the meningeal vessels be ligated and that only venous oozing be controlled by gauze packs.

Technique of Craniotomy

The technique of craniotomy as it is employed today has become a rather standard technique. One of two types is used. When a large area of the cerebral hemisphere is to be uncovered, the osteoplastic-flap craniotomy is employed. When a limited area is to be uncovered, or structures within the posterior fossa are to be explored, the decompression type of craniotomy is used. The osteoplastic-flap type of craniotomy consists in reflecting a portion of scalp with the

underlying bone attached to the scalp and muscles in order that the bone may be replaced and held in position at the conclusion of the operation. The decompression type of craniotomy consists in reflecting or elevating the scalp and muscles for the removal of the bone with the rongeur, with no attempt to replace the bone that has been removed.

Anesthesia.—Neurosurgeons, like general surgeons, have experimented with various types of anesthetics. Those that are accepted today are as follows: Local anesthetics are used when limited procedures are employed, when patients are comatose, or when general anesthesia is contra-indicated. Intravenous anesthesia, pentothal sodium, may be used as an induction anesthetic and is of value in traumatic surgery when only a short anesthesia is indicated. Avertin, administered by rectum, supplemented with inhalation of ether, is preferred by a group of neurosurgeons. The anesthetic of choice for major neurosurgical operations, based on my own experience, is ether administered by inhalation. The technique consists of induction of anesthesia with nitrous oxide, followed by administration of ether by the drop method until the patient is thoroughly relaxed, at which time the Magill intratracheal tube is inserted. Anesthesia is maintained with ether, administered by the drop method on the open mask. This procedure permits an open airway without suffocation, an advantage which results in the use of a lesser amount of anesthesia, the avoidance of increasing the intracranial pressure by venous stasis and the facilitation of the use of oxygen in the event it becomes necessary in controlling surgical shock.

Asepsis.—Aseptic technique is an important factor in all surgical procedures performed on structures within closed cavities of the body. Its importance cannot be over-emphasized in neurosurgical operations, since structures of the central nervous system are extremely vulnerable to infection.

Hemostasis.—The achievements of cerebral surgery bear a direct relationship to the improvement in methods for the control of bleeding. It is amusing to review the literature which describes the means that surgeons in the early days of the specialty resorted to in the control of hemorrhage during craniotomy. Today, scalp bleeding is controlled with a hemostatic clip. Few surgeons still employ the compression method by applying Kelley forceps to the galea. Bone bleeding is controlled by applying wax to the cut surfaces of the bone. The wax most universally used is prepared after the formula suggested by Horsley. Meningeal bleeding is readily controlled by silver clips which were introduced by Cushing. Silk ligatures employed for the larger vessels, whether arterial or venous, have continued to be extremely effective in controlling hemorrhages. Electrocoagulation has proved most effective and is a substitution for silver clips and ligatures for the control of smaller blood vessels in the scalp, muscles, dura and cortex. Electrocoagulation has added a valuable factor in the removal of encapsulated tumors, since it has made possible the removal of these tumors piecemeal through a very small opening; whereas previously these same tumors had to be considered as inoperable.

Elevation of Bone Flaps.—The technique of elevating bone flaps has likewise gone through a series of changes. The accepted procedure today consists of making several trephine openings at the margin of the proposed flap, after which the intervening bone areas are cut with a Gigli saw. The base of the flap is usually broken by elevating the peripheral margin of the flap. A variety of drills has been invented for the purpose of making the trephine openings. Osteotomes and skull plows have also been devised. However, when one takes into consideration the time factor necessary to adjust these various electric appliances, it becomes apparent that the bone flap can be elevated more quickly by the use of sharp cutting burs and a good steel saw than by the use of the various electric drills and saws.

Closure of Flap.—As neurosurgeons have become more interested in the removal of tumors than in the performance of a craniotomy, changes have been made from time to time in the selection of incisions and shapes of various osteoplastic flaps, in order to facilitate a more direct approach to the neoplasm. Fewer negative explorations result from the better localization of cerebral lesions. Though decompressions are still resorted to, precautions are taken to avoid cerebral herniations. In the event a decompression becomes necessary following an osteoplastic-flap

craniotomy, the bone is removed at the base of the flap over the temporal lobe, but the remaining portion of the bone flap is wired into place. In order to avoid cerebellar hernias, extreme care is taken to close the structures on anatomic planes with interrupted sutures of silk.

Control of Intracranial Pressure.—The control of intracranial pressure during a craniotomy has always been a perplexing problem. The aspiration of a dilated lateral ventricle invariably suffices. In the event the neoplasm is of such size as to have compressed the ventricles and subarachnoid spaces, hypertonic solutions of dextrose have been necessary as a rule to prevent disastrous results during the operation. However, with the use of the intratracheal tube in administering the anesthetic, the problem of controlling the increased intracranial pressure has been greatly minimized owing to the fact that venous congestion of the cerebral veins and sinuses has been markedly reduced because of the open airway afforded during the anesthetic.

Shock.—Surgical shock results from loss of blood at the operative site, loss of fluids, loss of proteins into the tissue, and exposure and trauma of the structures in the surgical field. The fall in blood pressure accelerates the phenomenon of shock and brings about a state of anoxemia. Thus it is the duty of the surgeon to operate expeditiously, maintain the fluid balance (supplementing blood or plasma if necessary), and administer oxygen along with the air during the anesthesia. Surgical shock is best controlled before it develops. If the craniotomy proposed is to be a major affair, it is wise to begin the intravenous infusion of physiologic salt solution and dextrose before blood pressures begin to recede.

Purpose of Craniotomy

Craniotomy originally was designed to resect or decompress cerebral neoplasms and to drain abscesses of the brain. However, today it also is employed to gain access to other diseased structures within the cranial cavity. Among the lesions that are being attacked in this manner are aneurysms of the cerebral vessels. The one most effectively controlled is the arteriovenous fistula between the internal carotid artery and the cavernous sinus, which gives rise to a pulsating intracranial mass situated in the middle fossa and produces intracranial symptoms, a pulsating exophthalmos, oculomotor palsies and blindness. The treatment employed is the control of the arteriolar flow into the pulsating vascular mass, after having assured oneself that it is possible to obliterate the flow of blood through the internal carotid artery on the side of the lesions without producing a contralateral hemiparesis. Although it is possible in a number of cases to control the symptoms by ligating the internal carotid artery in the neck, neurosurgeons are frequently called upon to trap the arteriovenous fistula. This is done by ligating both the external and internal carotid arteries in the neck, followed by an intracranial ligation of the internal carotid artery on the cerebral side of the fistula before cerebral vessels are given off. In addition, I have found it necessary to obliterate the ophthalmic artery from within the cranium to prevent the reverse flow of arterial blood into the cavernous sinus through the arteriovenous fistula. I also have found it an advantage to do a venousectomy on the ophthalmic veins to reduce further the exophthalmos. Even though the ophthalmic artery has been ligated, in addition to the internal carotid, I have learned that the vision was preserved.

Aneurysms on other cerebral vessels have been resected. It must be borne in mind that such procedures cannot be carried out promiscuously unless there is the assurance of adequate collateral circulation. Arteriovenous varices of cerebral vessels occasionally are amenable to ligation and electrocoagulation.

Lobotomy

Lobotomy as a surgical procedure in the treatment of insanity represents one of the newer phases of neurosurgery. It was initiated by Moniz and brought to the fore by Freeman and Watts. The operation is now being performed by several neurosurgeons in various clinics. The operation is performed through a trephine opening over the premotor area and is designed to interrupt most of the fibers which pass between the frontal lobe and the midbrain. The object of the operation is to diminish the incoming impressions which give rise to the aberrations of mental reaction, characterized by disturbed mental states. Although the procedure is still in the investigative state, it does appear that certain

results have been accomplished. The two types of mental states most favorably affected are those of compulsion neurosis and involutional melancholia. Perhaps the postoperative interval is not of sufficient duration to evaluate the final results. One investigator made the comment that it was his opinion "that it made certain crazy individuals less crazy."

Premotor Resection

Premotor resection for Parkinson's disease is another one of the new neurosurgical operations. Klemme is the chief exponent of this procedure. According to his report on unilateral lesions, worth-while results have been accomplished. Unfortunately other surgeons have not been so successful. It is difficult at this time to evaluate the results accomplished. Since there are many sufferers of this disease, further investigation is justified. However, it should be borne in mind that a high morbidity accompanies the operative procedure.

Neuralgia

The major neuralgias, trigeminal neuralgia and glossopharyngeal neuralgia, have come to be known as distinct clinical entities. Each presents a definite syndrome. Palliative relief can be obtained in the treatment of trigeminal neuralgia by the injection of the peripheral branches with concentrated alcohol. This is not true in the treatment of glossopharyngeal neuralgia, since it is impossible to inject the ninth cranial nerve without injecting other nerves, such as the vagus, which lies in close proximity to the glossopharyngeal nerve. Peripheral avulsion as a surgical procedure in the treatment of trigeminal neuralgia has been abandoned with the exception of that of the ophthalmic branch, since the alcohol injection has proved more effective than the avulsion. Since both diseases are similar in characteristics, with the exception that they involve separate nerves, the attacks of pain will return unless the sensory component of each nerve is sectioned within the cranium. A resulting anesthesia must be accepted by the patient. The sensory root of the fifth cranial nerve may be subtotally or totally divided by either a transtemporal or a suboccipital approach. Although arguments are put forth to support the respective approaches, it appears that the transtemporal approach is the preferable one, since it is more universally employed by neurosurgeons. The unilateral, suboccipital approach to the ninth cranial nerve is the procedure employed in dividing this nerve in the treatment of glossopharyngeal neuralgia, since no other approach affords access to the intracranial portion of the nerve. In order to diminish the paresthesia that occasionally follows the section of the sensory component of the trigeminal nerve in elderly individuals, Sjöqvist devised and performed a tractotomy, sectioning the fibers of the fifth cranial nerve in the pons. Unfortunately, this operation did not achieve the objective for which it was designed, although it did relieve the trigeminal neuralgia. The postoperative sequela, which included cerebellar disturbance, limited the usefulness of the operation.

Subarachnoid Injection of Alcohol.—Subarachnoid injection of alcohol is a useful procedure in a limited number of painful conditions resulting from metastasis and herpes zoster. Unfortunately, there still exists a variety of neuralgias that are not amenable to surgical treatment, a fact which offers a challenge to investigators in this field. The more common ones are the so-called intercostal neuralgias, sphenopalatine neuralgias, and the multiple neuralgic pains that follow the extraction of teeth. Painful stumps and causalgias still present problems that are asking for solution. Occasionally, relief is obtained by the amputation of a neuroma and the injection of a nerve with alcohol. A sympathectomy offers some relief. Chordotomy, a procedure which is designed to section the spinal thalamic tract of the spinal cord in order to relieve painful sensation, has proved of value in the treatment of pain resulting from metastasis, but since subarachnoid injection of alcohol is a simpler procedure and is frequently effective in relieving pain, it has come to replace the major procedure to a great degree.

Tumors of the Spinal Cord

Tumors of the spinal cord occur much more frequently than was formerly thought. During the past twenty-five years, the neurologist has done much to elucidate the symptom complexes that result from the various types of intraspinal tumors which produce pressure on the spinal cord or invade it. The pathologist has likewise shown that most of these tumors are nonmalignant. He also has shown that the ependymal cell glioma arising from the filum terminale, does

not metastasize and that cures can be effected if it is completely removed.

Since 80 per cent of the intraspinal tumors are benign, their growth is slow, which accounts for the slow development of clinical symptoms. Tumors may be situated within the spinal canal, but extradurally. The largest group is situated within the dura, but extramedullary. The smallest group is situated within the spinal cord itself. The tumors most frequently arise from the meninges and nerve roots. They may arise from any of the structures within the spinal canal. When they are attached directly or indirectly to a nerve root, root pain is the first symptom to appear. As their growth proceeds, localized pressure and displacement of the spinal cord take place, which produce symptoms that indicate the nerve tracts involved. If the lesion is not recognized, the tumor may grow to such a size as to compress completely the spinal cord and produce the classic picture of transverse myelitis. This phenomenon helps to distinguish intraspinal tumors from inflammatory and degenerative processes. Spinal puncture, the elicitation of the presence or absence of spinal subarachnoid block, Queckenstedt test, as well as the radiologic study of the osseous structure of the spinal column, myelographic study and radiographic study of the opaque oil within the arachnoid space of the spinal canal are valuable adjuncts in making an accurate diagnosis. Thus it is obvious that the sooner a tumor is recognized and removed, the less damage it will do and the better will be the postoperative results.

Protrusion of Intervertebral Disks

Although protruded intervertebral disks are the result of injury to the annulus fibrosus with partial or complete prolapse of the nucleus pulposus, they have undoubtedly existed for all time but have only recently become recognized as a common cause for low back and sciatic pain. Occasionally, these lesions appear in other portions of the spinal column and produce symptoms not unlike those of an intraspinal, extradural tumor. Those that appear in the cervicodorsal region, which are second in frequency to those that occur in the lower lumbar region, are invariably the result of severe trauma. Again, the recognition of these lesions was originally due to myelographic studies. Lipiodol was the first opaque substance used to identify these lesions. It is still used, but since there is some question as to the irritation it may produce, the oil is removed at the conclusion of the test. Air and oxygen and even helium have been substituted for lipiodol in the myelographic studies. More recently, a substance called pantopaque, which can be removed more readily than lipiodol, is being employed to localize and identify the lesion.

Undoubtedly, the occasional injury, with the resulting incomplete protrusion, heals spontaneously, but more often than not the symptoms recur. Surgical intervention then is necessary. Formerly the protruded mass was removed through a bilateral laminectomy; now we have learned that it can be removed through a limited unilateral laminectomy; and occasionally, as Doctor Love has suggested, it can be removed without a laminectomy after removing the hypertrophied ligamentum flavum that resulted from the original injury.

The question of whether or not a bone graft should be inserted at the time the protruded portion of the disk is removed has been a subject of much discussion. Inasmuch as we have had the opportunity of observing a large number of cases in which protruded disks were removed without fusion and with fusion, we have come to the conclusion that fusion should be combined with the removal of the protruded portion of the disk when there is present an anomaly of the lower lumbar vertebræ, such as sacralization of the fifth lumbar vertebra, malformations of the arch of the fifth lumbar vertebra, beginning spondylolisthesis and active hypertrophic arthritis.

Occasionally it is advisable to perform a combined operation when there is a history of long-standing static backache in addition to the symptoms produced by a protruded intervertebral disk. Furthermore, it occasionally is advisable to perform a combined operation on a patient who is a laborer, who is compelled to perform unusual, heavy work, such as one who handles freight or one who is a stone mason. The results achieved by operation are in direct proportion to the irreparable damage produced by the protrusion of the nucleus pulposus. They are inversely proportionate to the amount of industrial compensation and disability insurance sought by the individual.

Operations on Peripheral Nerves

Operations on the peripheral nerves were formerly limited to the repair of the injured nerve. Today their scope has extended to include

esions of the sympathetic nervous system. It is generally accepted that the ideal repair of an injured nerve is an end-to-end anastomosis after resecting the neuroma. The apposition of the nerve ends is maintained by interrupted sutures of fine silk. The surgical field must be dry and free from sepsis. The ideal time to anastomose the nerve is six weeks after all evidence of infection has disappeared. Occasionally, one has to take advantage of flexion and adduction of extremities and even the transfer of nerves in order to bring about an approximation of the nerve ends. When it is impossible to bring the nerve ends together, autogenous cablegraphs or tubes of various substances have been employed to encourage the outward growth of axones. Unfortunately, the distance cannot be too great; if it is much more than a centimeter, cicatricial changes take place before the axones reach the distal portion of the nerve. If there is a preponderance of scar tissue, one should attempt to place the sutured portion of the nerve in a new muscle plane.

As the physiology of the sympathetic nervous system becomes better understood, it appears that vasoconstrictor impulses passing over gray rami are responsible for vasospastic disorders affecting the peripheral vessels of the extremities, which gives rise to such disease as Raynaud's disease and other peripheral vascular disorders that are aggravated by vasospasm. This being true, a variety of operations has been devised and employed to interrupt these impulses and thus relieve or ameliorate the symptoms produced by vasospasm.

Sympathectomy

The control of essential hypertension without renal involvement has likewise interested the neurosurgeon and prompted him to devise procedures for sectioning splanchnic nerves, including the two upper lumbar sympathetic ganglia on both sides, with the hope of interrupting the vasoconstrictor impulse to a large vascular bed, thus creating a reservoir and a safety valve. This procedure is probably one of the steps in an attempt to control essential hypertension. The results justify the continuance of this procedure in select cases until such a time that an antipressor substance may be developed and given safely with effective results.

Summary

The object of this discussion has been to review some of the progress made in neurosurgery and to indicate the scope which it may include. I am aware of its limitations but am likewise aware that the specialty is still in its infancy. Surgical indications may be altered, procedures undoubtedly will change, new procedures will arise, and a more accurate selection of surgical lesions will be made with the hope that more will be achieved with each operation performed.

SIGNS OF MENTAL SICKNESS TAUGHT MILITARY POLICE

Teaching the military police to recognize signs of incipient mental and emotional sickness in able-bodied soldiers is one of the war aims of the National Committee for Mental Hygiene, Dr. George S. Stevenson, medical director of the committee, reported at its annual meeting in New York.

The M.P.'s and also Red Cross workers, physicians in the armed services, company officers, chaplains, USO, Special Services (morale), and instructors are in a position, Dr. Stevenson said, to see the signs of an impending break in mental health and to see that the soldier gets special attention before he reaches the stage of serious mental sickness requiring hospitalization.—*Science News Letter,* December 5, 1942.

PROGRESS IN THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE UROGENITAL TRACT

GILBERT J. THOMAS, M.D.
Minneapolis, Minnesota

THE successful and continuous publication of a scientific magazine of the calibre of MINNESOTA MEDICINE for a period of twenty-five years is an accomplishment about which the members of the State Medical Association should be proud.

MINNESOTA MEDICINE was conceived during the period of our participation in the last World War. It flourished during this difficult period and now, after twenty-five years of successful publication, we find ourselves again confronted with the difficult job of publication during a total world-wide war.

The papers, monographs, case reports, and other scientific material appearing in this magazine are carefully selected and edited. They contain useful information for the general practitioner as well as the specialist. The editorials and news letters from the officers are informative and keep the busy practitioner enlightened concerning medical economies and other subjects that are related to the ethical practice of medicine. A glance at the abstract sections of some of our leading national magazines frequently reveals abstracts of selected articles that have been published in MINNESOTA MEDICINE.

The present editorial staff of the journal has done an excellent job. The work of editing, which is sometimes onerous and always time-consuming, receives little or no notice or commendation from the membership. I take this opportunity of personally congratulating Dr. Carl B. Drake and his staff.

My contribution to this Anniversary Number will deal with a short review of the progress that has been made in the diagnosis and treatment of a few medical and surgical conditions that arise in the urogenital tract.

One of my first papers published in MINNESOTA MEDICINE was concerned with renal infections. This paper contained data obtained during my attempt to classify the bacteria that were identified when cultures were made from infected urine specimens. One important fact that I learned during this clinical research was that cultures made from specimens of urine obtained at this time and for the purpose of this investigation were not always uncontaminated because instruments and ureteral catheters might not be completely disinfected or sterilized. One conclusion that I formulated was that the bacteria obtained by culture from one specimen of urine might contain secondary invaders and not the primary infecting organism. During the twenty-five years that have elapsed since my attempt to add something to our then incomplete information about bacterial causes of renal infections, great advances have been made not only in the more accurate diagnosis of the bacteriological cause of renal infection but in the treatment of this condition.

The first advance that speeded our ability to successfully cope with renal infection was the development of an improved sterile technique for obtaining specimens of urine for culture. The next advance was made by bacteriologists who were able to make accurate differential diagnoses of the type and strain of bacteria present after a careful study of the cultural characteristics of the bacteria they grew on various media from specimens of urine obtained with aseptic technique. This feat was particularly useful to the urologist and the clinician when differential diagnosis of the various strains of colon bacilli was accomplished. This was achieved by accurate observation of the behavior of colon bacilli in the production of gas and in the acid-alkaline reaction of culture media that contained sugars.

Another contribution to the control of and sometimes the cure of renal infections was the observation of the effect that change in the physical properties of the urine has on bacterial growth.

The surface tension of the urine was changed by the oral administration of certain drugs that were eliminated in great part in the urine. This physical change in the urine did produce bacteriostasis in many instances and a bactericidal action in many. However, this physical change was not always produced by the drugs used for this purpose and when it was, bacteria were not always killed.

Another advance was made in the successful

control of renal infection when careful observation of the physical properties of the urine disclosed that certain bacteria were most often found in urine whose hydrogen ion concentration was high while other bacteria were found only when the reaction of the specimen was definitely acid and the hydrogen ion concentration was low. The physiological chemist and the bacteriologist working together have determined that some bacteria grow best in acid urine while others grow best in alkaline urine. Following this observation the urologist has been able to control, and sometimes eradicate, the growth of bacteria in the urine by changing the pH and the reaction of the urine by the oral administration of drugs and foods. Examples of the drugs used are mandelic acid, its various chemical combinations, and ammonium chloride and nitrate. The ketogenic diet, when properly composed by the dietitian and carefully followed by the patient, will produce physical changes in the urine that are bacteriostatic and sometimes bactericidal to most strains of colon bacilli. The production of a high pH of the urine so that it is very alkaline will cause bacteriostasis of the coccus group of bacteria, with some exceptions.

For many years all physicians used hexamethylenamine when any type of renal infection was present. The efficiency of this drug was improved when the pH of the urine was sufficiently changed to the acid side. This change in physical properties of the urine when hexamethylenamine is being used produced a breaking up of the chemical composition of this drug so that formaldehyde is free in the urine. This is the part of the drug that produces bactericidal action.

During the years that these observations were being made many urinary antiseptic drugs were manufactured, many of them from the coal tar dyes. The efficiency of these was based upon their effect on bacteria in a test tube. The clinical trials to determine the efficiency of these drugs as bactericidal agents acting in the tissues and fluids of the human body were and are disappointing. Occasional brilliant results were obtained but their mode of action is not well understood and the results obtained are not satisfactory.

When drugs were not completely effective some success was obtained in the treatment of severe renal infections when mild "shock therapy" was used. The stimulation of the reticulo-endothelial system produced severe reactions and a few fatalities were reported, but this type of therapy did remove bacteria from the tissues of the kidneys and from the urine. Killed bacteria, particularly the typhoid bacillus, were and are being used for this purpose.

Chemotherapy in the form of the sulfonamide drugs constitutes the greatest advance that has been made in the treatment of renal infections. These drugs can be absorbed in sufficient concentration in the blood serum so that they control the foci that may constantly or intermittently infect the kidneys via the blood stream and in addition their accumulation and elimination in the urine is a factor that makes them ideal urinary antiseptics. Careful checks of the drug concentration in the blood serum and the urine provide a method of determining correct and efficient dosage and the chemical changes that may occur in the human body that make these drugs inert in certain individuals. Although the sulfa drugs are the best agents we now have for combating renal infections, the best results following their use will be obtained only if the physician knows how to use them. Volumes have been written regarding the chemotherapeutic uses of the sulfa drugs. The subject is a complex one and the clinical use of these drugs by the uninformed, inexperienced clinician may do harm when good was intended.

Beginning at about the time that Minnesota Medicine appeared on the horizon of medical publications, I became interested in the diagnosis and treatment of lesions of tuberculosis that were found in the urogenital tract. At the same time I was offered an opportunity to study tuberculosis at Glen Lake, the County Sanatorium for Hennepin County. Since my return from the last war, I have continuously carried on a clinical research at Glen Lake Sanatorium, which I believe has added something to the information that we then had concerning urogenital tuberculosis. The method of treating renal tuberculosis today is much different from that prescribed twenty-five years ago. The first bit of information that we obtained from our clinical research was and is that lesions of tuberculosis in the urogenital tract are local manifestations of a general disease. The disease tuberculosis starts in the chest cavity, most often in the lung, where the primary lesions are located. From here, spread of the disease occurs via the thoracic duct and then the blood

stream. When spread occurs in this manner, we have a generalized disease because bacteria or infected emboli may be carried by the blood stream to any organ or tissue in the body. When this fact was thoroughly established in our minds, we realized that lesions of tuberculosis found in the kidney or other urogenital organs must be tiny to begin with and do not all progress to destruction of the kidney and crippling of other urogenital organs.

When we realized that tuberculosis of the kidneys was a secondary lesion, a local manifestation of a general disease, and that infection may be present in the kidneys for a long period of time before symptoms are produced, our next step was to determine how many individuals who had pulmonary tuberculosis had clinical evidence of urogenital lesions. This led us to the routine examination of the urine of every patient in the Sanatorium who had an active lesion of tuberculosis. This examination revealed that 4.1 per cent of all patients with pulmonary or other lesions of tuberculosis had bacilli of tuberculosis in their urines or other clinical findings of this infection in the kidneys. The urological examination of patients who had cellular elements or bacilli of tuberculosis in their urines revealed that many had demonstrable small lesions in their kidneys that could be visualized on the pyelo-ureterograms without objective symptoms suggesting the presence of renal lesions of tuberculosis.

As our clinical research progressed, we began special pathological examinations of the material obtained at autopsy and following the surgical removal of kidneys. In addition, we began the examination of the viscera of a large number of guinea pigs that had been injected with the human strain of bacilli of tuberculosis. At about the time this part of our research was undertaken, Dr. E. M. Medlar published his observations concerning the pathology of tuberculosis of the kidney. This work established the fact that renal tuberculosis was hematogenous in origin and practically always bilateral and that certain lesions in the kidney might heal and that small lesions of tuberculosis could be present in the kidney without producing symptoms.

In 1917, tuberculosis of the kidney was not suspected until the patient had symptoms of bladder involvement such as frequency, painful or burning urination. Little or no attention was paid to the general condition of the patient, and all patients were submitted to surgical treatment unless active pulmonary lesions were present.

We are learning new things each day from our continued clinical research. We believe, however, that definite progress has been made in the diagnosis and treatment of renal tuberculosis during the last twenty-five years. I am quoting herein the conclusions that I published in an article written for the International Congress of Urology. These contain some statements that suggest the advances that have been made in the diagnosis and treatment of renal tuberculosis.

"There is an early as well as a late stage of renal tuberculosis just as there is in any other type of tuberculous infection. This period may be symptomless, but a careful search will reveal clinical findings that are sufficient for a diagnosis.

"A study of the early lesions of renal tuberculosis must be undertaken while the patient is under treatment in a sanatorium. It is during the active stage of the original pulmonary or other lesions of tuberculosis that the kidney becomes infected and the early lesions develop.

"Any patient with pulmonary or other lesions of tuberculosis may have an unrecognized renal involvement (4.1 per cent in our series of cases). Repeated urinalyses, the injection of urinary sediment into animals, and complete urological studies should be made before a negative diagnosis is given.

"The route of spread of bacilli of tuberculosis from the chest cavity to the kidney is via the blood stream.

"A normal kidney does not eliminate bacilli of tuberculosis.

"The local renal lesion produced by bacilli of tuberculosis is not a local disease but a local manifestation of a general disease.

"The organs and tissues of the human body may develop resistance against the bacillus of tuberculosis that may be manifest in the kidney as well as elsewhere.

"The progress of lesions of tuberculosis of the kidney as well as elsewhere is slow.

"Tuberculosis of the kidney does not present a pathological picture different from tuberculosis of other organs. When one studies tuberculosis of other organs or tissues, this fact becomes apparent.

"Bilateral renal infection occurs in between 47-51 per cent of all patients who have urogenital tuberculosis (60-70 per cent during the invasion stage). Repeated examinations including bilateral pyelo-ureterograms are necessary to prove the absence of nondestructive tuberculous lesions in an apparently sound kidney.

"The primary focus of tuberculosis in the urogenital tract is most often the kidney. Early urogenital tuberculosis is usually a symptomless disease.

"Pyelo-ureterograms may show definite evidence of a pathological lesion in a kidney when the examination of the urine for bacilli of tuberculosis from this kidney is negative.

"Bilateral pyelo-ureterograms are major factors in

making a positive diagnosis of renal tuberculosis in 27 per cent of instances. They are valuable in following the progress of destructive lesions.

"The finding of bacilli of tuberculosis in catheterized ureteral urine from one kidney does not in itself constitute an indication for nephrectomy even if the urine from the other kidney is negative.

"Treatment for every case of renal tuberculosis is both medical and surgical. How long the medical treatment should be instituted before surgical treatment is started depends entirely upon the condition present and the care with which the diagnosis has been made.

"Clinical and pyelographic evidence indicates that a nondestructive lesion of renal tuberculosis will heal. A patient with this type of lesion should have the advantage of sanatorium treatment to assist him in building up the necessary resistance against the destructive effect of the bacillus of tuberculosis.

"Before attempting the removal of one kidney known to contain a lesion of tuberculosis, be sure that the other kidney is sound and other lesions of tuberculosis are arrested. This may require months of observation and repeated animal inoculations of urinary sediment.

"Every patient who has submitted himself for surgical removal of a tuberculous kidney should have medical treatment following the surgical operation.

"The prevalence of renal tuberculosis is decreasing.

"The character of lesions of renal tuberculosis is changing."

During our investigation at Glen Lake Sanatorium, which was aimed primarily at the diagnoses and treatment of lesions in the kidney, it became necessary to examine the whole urogenital tract. A review of the data found in the reports of complete urological examinations and careful clinical examination and observation of our patients who had lesions in the genital tract changed some of the opinions that had been expressed by other observers concerning the route of invasion and the route of spread of tuberculosis to and in the urogenital tract.

In a paper published in Minnesota Medicine in May, 1940, we listed the following conclusions. Although some of these are not accepted by urologists generally, our continued observations support these conclusions.

"Tuberculosis of the genital tract is a local manifestation of a general disease and lesions here are most often secondary to a primary urinary tract infection in the kidney. The treatment plan of the local genital lesion or lesions must be based on this pathological fact.

"The route of spread from the kidney to the genital tract is most often via the urine.

"The primary lesion in the genital tract is most often the prostate gland. From here the infection may spread to the other genital organs. Foci of tuberculosis in the prostate gland may produce no symptoms.

"The seminal vesicle is infrequently infected with the bacilli of tuberculosis and is most always associated with lesions of tuberculosis in the prostate gland.

"Tuberculosis infection in the epididymis is secondary in the genital tract to tuberculosis in the prostate gland. There may be a subacute stage of tuberculosis of the epididymis which is activated by trauma.

"Treatment of lesions of tuberculosis in the genital tract consists of:

(a) The location and arrest of other lesions of tuberculosis and of the primary focus in the urinary tract by whatever means are necessary.

(b) Hygienic treatment of lesions of tuberculosis in the epididymis and heliotherapy to be followed by application of heat, incision and drainage, and surgical removal when indicated.

(c) Orchidectomy is rarely necessary.

(d) Hygienic treatment for tuberculosis of the prostate gland and seminal vesicles after removal or arrest of other active foci in the urogenital tract is always practiced. Surgical removal of these organs is seldom necessary.

(e) Postoperative rest for three months is always essential."

One of the early articles published in Minnesota Medicine was concerned with the diagnosis and the treatment of hypertrophy of the prostate gland. This was written by a general practitioner in 1917 and was an excellent article. The author of this article asked that practitioners prepare their patients for surgical treatment by complete and prolonged drainage of the urinary bladder before they submitted them for surgical treatment for hypertrophy of the prostate gland. This writer did not discuss the merits or demerits of one or the other methods of surgical removal of the gland.

The progress that has been made in the treatment of this condition during these twenty-five years constitutes one of the most important contributions in the field of surgery. The first important forward step that was taken toward reduction of morbidity and mortality in the treatment of patients with prostate gland hypertrophy was the careful pre-operative appraisal of the patient's physical condition, particularly the function of the kidneys, heart muscle and vascular system. This was followed by the careful preoperative preparation of patients preceding surgical treatment. This consisted primarily of drainage of the urinary tract via the bladder. Mortality and morbidity rates were reduced from approximately 25 to 5 per cent or less when urological surgeons began to apply pre-operative preparation.

At this time there was still a lively controversy between the apostles of perineal and suprapubic postatectomy. The pre-operative care, however, affected the mortality equally when one or the other of these surgical treatments was applied.

After the mortality rate associated with prostatic hypertrophy was reduced below 5 per cent, the makers of surgical instruments of precision for inspection of the bladder, added parts to these instruments so that transurethral resection of the prostate gland might be accomplished. Many different kinds of instruments were used and these were divided into two main groups: those that used a wire loop or round knife activated by means of a high voltage electrical current that would produce cutting in water, and those that used a round coring type of sharp steel knife that would remove sections of tissue when they were engaged in a fenestrum near the end of the sheath of the instrument. The currents used for cutting under water have been constantly improved and the instruments for using the activated loop have been so improved that the partial or complete removal of the prostate gland by this route has become the method of choice in the hands of many urologists.

Some conservative urologists who watched the constant lowering of the morbidity and mortality rates which occurred with improvement in the technique of pre-operative care of these patients, still adhere to the open method of surgical removal. They find certain types of enlargement and many patients whose general physical condition suggests that in their hands the patient would be more safely handled by open surgical removal. Most urologists have fitted the transurethral method of removing the prostate gland into their armamentarium, but do not remove all prostate glands in this way. Some urologists have so thoroughly mastered the technique of transurethral resection that all prostate gland hypertrophies are removed by them in this manner.

The transurethral or resection method has become the method of choice for removing the obstruction at the bladder neck associated with malignant changes in the prostate gland. There is no doubt that transurethral resection has permitted many patients to live in comfort and urinate near normally for many more years than would have been their lot had a suprapubic drain been introduced and the prostate gland received no treatment.

A urologist has recently proved the relationship between malignant growths in the prostate gland and the gonads in the male. The use of male anti-gonad, or female gonad, or like chemical substances has controlled the progress of malignant growths in the prostate gland, has reduced the size of the metastatic growths, has improved the general condition of most patients and in many instances has relieved them of distressing pain, especially that from metastases that have involved the bones of the spine, the pelvis and the adjoining nerves. This gonad substance may be given by mouth.

Brilliant results have been obtained following the surgical removal of both testicles in the relief of pain produced by multiple metastases. Bilateral orchidectomy produces a break in the gonad control of and the stimulating effect on the growth of certain cells found in all malignancies of the prostate gland that are gonad related.

The biochemists have isolated an enzyme that may be elaborated by gonad-related malignant cells that occur in the prostate gland and in bone metastases. The amount of this enzyme in excess of normal can be determined by analysis of the blood serum. Its presence in more than normal amounts suggests bone metastases and the blood level of this enzyme furnishes a gauge of the growth increase or recession of these metastatic lesions.

This advance in the treatment of carcinoma of the prostate gland has not produced cures of this fatal and crippling disease of older men. It has, however, produced some brilliant results in the relief of pain, improvement in the patient's general condition, and a definite change in the character of the malignant growth. If we remember that 25 to 30 per cent of all men who have symptoms of hypertrophy of the prostate gland have demonstrable malignant changes in their prostate glands, we can realize how important this advance in the treatment of this condition becomes.

Ferrets, apparently susceptible to the common cold, make good subjects for research.

PROGRESS IN ORTHOPEDIC SURGERY

MELVIN S. HENDERSON, M.D.
Rochester, Minnesota

IN the fifth to the tenth centuries, both crippled children and adults were neglected and abused; their plight was regarded as divine punishment and no sympathy or understanding was extended to them. The Renaissance slowly brought into being new thoughts and facts; social science gradually emerged into being in the seventeenth and eighteenth centuries. To her everlasting credit, England led the way in concluding that government owed something to the poor and unfortunate. At present, in our own State of Minnesota, provision for the care of the crippled child leaves little to be desired.

Orthopedic Facilities in Minnesota

The first number of MINNESOTA MEDICINE was published in January, 1918. The first original article in that issue was written by Drs. Arthur J. Gillette and Carl C. Chatterton. It dealt with the orthopedic treatment of deformities resulting from incurable paralysis. Dr. Arthur J. Gillette, pioneer Minnesota orthopedic surgeon, was president of the Minnesota State Medical Association that same year and his presidential address was published in the October, 1918, issue of MINNESOTA MEDICINE.

The history of orthopedic progress in Minnesota is closely interwoven with the life work of Arthur J. Gillette. Soon after his entrance into the ranks of the medical profession, Dr. Gillette decided to devote himself exclusively to orthopedic surgery. True to the orthopedic surgeon's unwritten code that the crippled child is his chief charge and responsibility, Dr. Gillette labored with never-lagging energy in that child's interests; in so doing, he placed Minnesota first among the commonwealths of the United States in recognizing its duty to the frequently forlorn and neglected crippled child. As his influence and prestige increased, Dr. Gillette never forgot that obligation and he brought more pressure to bear on his friends in the legislative body of the state to provide better care and educational facilities for the crippled child.

As early as 1897, Dr. Gillette appeared before the legislators of the state appealing for state aid for the crippled child. Because of this appeal to the hearts of these men, and because they were swayed by the deep sincerity and earnestness of Dr. Gillette, he succeeded in awakening an interest in the problem of the indigent crippled child which has become traditional in that body and has never faded. There was no real precedent for this action and the legislators were treading on pioneer ground. In 1907, a grant was made to build a hospital for these children. The building was completed in 1911 and the children were transferred from the state owned ward at the City and County Hospital of Saint Paul (now Ancker Hospital) to their new home, the Minnesota State Hospital for Crippled and Indigent Children, located at Phalen Park. Dr. Gillette was the surgeon in charge until his far too early death on March 24, 1921, when he was but fifty-seven years of age. Soon after his death, the legislative body of the state changed the name of the hospital to The Gillette State Hospital for Crippled Children—a worthy tribute to its founder. Later was added Michael J. Dowling Memorial Hall, of which I shall say more later. The hospital is a comfortable, serviceable building of the one-story, pavilion type and is under the superintendency of Miss Elizabeth MacGregor. Dr. C. C. Chatterton is now the surgeon in charge. The hospital accommodates more than 250 patients, who receive the best services known to medicine and surgery.

The Shriners' Hospital for Crippled Children was built and opened in Minneapolis in 1923, on East River Road, adjacent to the Saint Paul city limits. Dr. Wallace Cole has been chief surgeon there since the founding of the hospital. This project reflects great credit on the "playground of Masonry," the Order of the Mystic Shrine; it supplies concrete evidence of an increased appreciation among men that social obligation must be recognized and met.

By the early and middle twenties the number of surgeons in Minnesota confining their work to orthopedic surgery gradually had increased. On September 30, 1924, at the home of Dr. Emil Geist, who died in 1933, the Minnesota Ortho-

From the Section on Orthopedic Surgery, The Mayo Clinic, Rochester, Minnesota.

pedic Club was organized with Dr. Geist as its first president. Its purpose was to furnish a medium through which Minnesota surgeons who were interested in orthopedic surgery might exchange ideas. The members recognized their responsibilities to the public and provided physicians to conduct clinics, which were being organized about the state, to bring to light the crippled and arrange for their care. In 1934 the membership was opened to include orthopedic surgeons from the Dakotas and the name of the organization was changed to the Minnesota-Dakota Orthopedic Club.

In 1928 a significant event bearing on orthopedic surgery occurred at the University of Minnesota. Folwell said it was an event illustrative of "how a university whose primary function is to enlarge knowledge, including that of laws of health and the means of healing diseases may become the custodian and trustee of private endowments for charity." This statement was in reference to William Henry Eustis' gift of $2,000,000 for the establishment of the "Minnesota Hospital and Home for Crippled Children."

A peep behind the curtain into the life of the donor is interesting. Born in New York State in 1847 of English lineage, William Henry Eustis, at the age of fifteen years was afflicted with disease of the hip joint and became crippled for life. However, his spirit was undaunted; he pursued his education, graduated in law and came to Minnesota in 1881 to practice. Later he was mayor of Minneapolis and he dealt so successfully in real estate that he amassed a fortune. His own affliction led to his deep understanding of the handicapped, crippled child. He never married, had no heirs or close kin and his lot must have been, in many ways, a lonely one. He decided to do all he could for crippled children and his magnanimous gift was the result.

November 10, 1928, the cornerstone of the Minnesota Hospital for Crippled Children was laid. Dr. Charles H. Mayo, of Rochester, was the principal speaker on this occasion and he remarked that William Henry Eustis would be honored forever, not only as a benefactor of children but also as a great contributor to education and scientific progress. "He thought," said Dr. Mayo, "of future education in Minnesota when he stipulated that this hospital, his gift to unfortunate children, should be located at the University, the center of education in the State." Unfortunately Mr. Eustis was too ill to attend the ceremony and he died a few weeks later, on Thanksgiving Day. It was not long after this that the hospital became known as the Eustis Hospital for Children instead of by the name modestly suggested by the donor. At present this hospital, which is a wing of the University Hospitals, is used chiefly for teaching pediatrics—the words "crippled children," used in the original name of the hospital being employed in the broadest sense. This hospital, together with the facilities at the Gillette and Shriners' Hospitals, provides ample beds for both undergraduate and graduate teaching.

A few years previous to the time when Mr. Eustis made his gift to the University of Minnesota, he had turned over twenty-one acres of land on West River Road for the erection of the Michael J. Dowling school which was to be devoted to the care and education of crippled children. Public subscription of $50,000 to this fund, and a like contribution made by the legislature, provided funds for erection of the building. It is maintained as part of the educational system of the city of Minneapolis.

Michael J. Dowling's name is used for two institutions in Minnesota: the school at the Gillette Hospital and the school for handicapped children in Minneapolis. Mr. Dowling had a colorful and successful career—an inspiration to all who are physically handicapped. When fourteen years of age, as a result of exposure in a severe blizzard in Yellow Medicine County, he lost both legs, one arm and part of the other hand. Undaunted he fought for an education and later owned, managed and edited a newspaper; following that he became a successful banker at Olivia, Minnesota. Mr. Dowling was elected to the legislature and became speaker of the House of Representatives. Following the war of 1914-1918 Mr. Dowling visited hospitals in both England and the United States, demonstrating what a man could do without limbs.

Graduate Training.—Three-year fellowships for graduate training in orthopedic surgery are maintained at the University Graduate School of Medicine in Minneapolis and also at the Mayo Foundation in Rochester. At the termination of this period of training, when a thesis has been written and accepted, and the fellow has successfully completed written and oral examinations,

he receives his M.S. degree in orthopedic surgery. In the course of this three-year fellowship, each graduate student in orthopedic surgery in residence at the Mayo Foundation spends six months at Gillette State Hospital to obtain intensive training in the treatment of crippled children. In like manner, those fellows in residence at the University Graduate School of Medicine, in Minneapolis, come to the Mayo Foundation for six months or a year, for training in orthopedic diagnosis, particularly as applied to adults. A fellowship at the University of Minnesota is maintained through the gift of funds by the late Mr. and Mrs. H. S. Cole, parents of Dr. Wallace H. Cole.

In 1934, through the coöperation of the Section on Orthopedic Surgery of the American Medical Association, the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons, the American Board of Orthopaedic Surgery, Inc., was organized. The purpose of the American Board of Orthopaedic Surgery is to improve the practice of orthopedic surgery by establishing certain standards of training and achievement which must be attained by candidates before they are declared diplomates of that board. Such a board has no legal right to prevent the practice of orthopedic surgery by physicians who are not diplomates of the board, but by its moral influence it has been a definite aid in keeping the practice of orthopedic surgery on a high plane. At the present time Minnesota has fourteen diplomates of the American Board of Orthopaedic Surgery, Inc., who are practicing in the state. Other specialties have similar boards and all are joined together in an advisory board of medical specialties.

Social Science in Orthopedic Surgery.—In 1935 the National Security Act, a recognized advance in social science, was passed and the responsibility for administration of the federal funds provided for crippled children was placed in the Children's Bureau of the United States Department of Labor. In 1936 the Division of Services for Crippled Children under the Minnesota State Board of Control was organized to administer the funds appropriated in Minnesota as an extension of existing services under the National Security Act. Gillette State Hospital, Eustis Hospital of the University and Shriners' Hospital were providing hospital services but adequate follow-up services were lacking. Dr. Herman E. Hilleboe was appointed director and a system of follow-up and diagnostic clinics was organized about the state. When the hospitals above mentioned were overcrowded and a long waiting list existed, the bureau made arrangements for care of these waiting patients in hospitals in the Twin Cities, Duluth and Rochester, which had orthopedic surgeons on their staffs. In 1939 the Board of Control was eliminated by legislative action and its functions were assumed by the Department of Social Security of the State of Minnesota. The Division of Services for Crippled Children was then set up as a bureau in the medical unit of the Division of Social Welfare of the Department of Social Security and, as such, carries on today. It is functioning effectively now under the direction of Dr. Malvin J. Nydahl. The age limit of the crippled child treated under this plan has been raised to twenty-one years.

After the orthopedic surgeon has done everything possible for the cripple, he is usually requested to suggest some means by which the handicapped person can take his place in society and earn his own way. This raises the question of vocational adjustment and, by 1939, under the Social Security Act, assistance of this kind had been established in all forty-eight states, as well as in the Territories of Hawaii and Puerto Rico. Direct responsibility for the program is assigned to the State Boards of Vocational Education. To be eligible in Minnesota the applicant must be a resident of the state, sixteen years of age or older and have a permanent physical disability which results in a vocational handicap.

Thus we see that during the past twenty-five years Minnesota has lived up to her early history of interest in the care of indigent, crippled children and has provisions second to none for their welfare. We have every reason to be proud of this achievement.

Now what has orthopedic surgery contributed in twenty-five years to the campaigns against particular diseases?

The Orthopedic Attack on Certain Diseases

Tuberculosis.—In twenty-five years, the change in manner of practice of orthopedic surgery, and in the character and number of patients accepted for treatment, perhaps has been most outstand-

ing in tuberculosis. The wards of orthopedic hospitals were formerly well filled with patients afflicted with tuberculosis of the bones and joints. At present, these cases are so rare that instructors in teaching institutions experience difficulty in finding patients to present to their students. We see less tuberculosis of all types; the sanatoriums of the country are no longer filled with patients with pulmonary tuberculosis; tuberculous glands of the neck are very seldom encountered and tuberculous peritonitis is very rare. The chief reasons are that better living conditions exist and open tuberculosis is recognized earlier; the dairy herds have been rid of the tuberculous cow and the milk in most towns and cities must be pasteurized. In private practice among orthopedic surgeons, very few patients with tuberculous joints are seen.

Poliomyelitis.—Infantile paralysis still takes its toll but in Minnesota during recent years the disease has not been attended by the high death rate it carried in some earlier epidemics. Comparison of the end results of treatment of this disease is very difficult because of the great variation in the types and degrees of paralysis in different epidemics. Since President Roosevelt allowed his name to be used, and the date of his birthday to be set aside as the occasion for raising funds to make possible research into the causes, effects and treatment of infantile paralysis, large sums have been accumulated. These funds have been too large to be used advantageously in research alone, so a large portion is left in the hands of local committees to be utilized in the care of persons afflicted with this disease.

There appeared on the scene in America a crusader from Australia with her own theories about the manner of treating patients afflicted with infantile paralysis. At first Miss Kenny (called Sister Kenny because all Australian nurses are given that title) was not understood but, undaunted and convinced of the value of the treatment, she continued her travel and finally came to Minnesota with a letter of introduction to the author. I had known of her work through friends in Australia and some of them, who formerly would not accept her theory, had reversed their opinions and they wrote, stating they were convinced of the value of her method and urging that her work be given thorough trial in America. Very few patients with acute infantile paralysis are seen in Rochester and that was the type of patient Sister Kenny wished to treat and so demonstrate her method. My appeal to Dr. Wallace Cole to give Sister Kenny a hearing was granted and very shortly thereafter provisions were made by Drs. Cole and Knapp for Sister Kenny to begin her work at the University.

Previous to this time, little or no treatment usually was administered during the acute stages of infantile paralysis. Often serums, including human serum, were used but it was difficult to evaluate the results. Immediately following the patient's admission, Sister Kenny boldly treated the patients, irrespective of the degree of illness or pain. She systematically applied warm moist packs and she employed no splints or massage. Pain and spasm were relieved with astonishing promptness. If for no other reason than the relief of pain, Sister Kenny's method was an advance in the treatment of infantile paralysis. When the doubting ones examined the patients treated by Sister Kenny, for the early deformities occasionally encountered in this disease, they were not to be found. The Kenny method is established. Sister Kenny always has conducted her work under the supervision of the medical profession and she never has accepted for herself a fee for services. There can be no doubt of the integrity and honor of this public-spirited woman and Minnesota owes her a debt of gratitude. Sister Kenny, in return, freely acknowledges her debt to the National Foundation for Infantile Paralysis, the University of Minnesota, the city of Minneapolis and its public-spirited citizens. She is appreciative of the efforts of the men associated with her in Minneapolis, particularly of their scientific aid in attempting to clarify the terms she used and to explain the spasm in the affected muscles and other changes which she noted in the acute stages. The Center for Continuation Study at the University of Minnesota has arranged courses of instruction in the Kenny method and orthopedic surgeons, physical therapists and physical therapy technicians have come from all over the United States and Canada to attend these classes. Minnesota has taken the lead in this phase of orthopedic teaching.

Osteomyelitis.—A dread disease which frequently affects children is osteomyelitis. Teaching concerning its treatment has been modified. Formerly it was regarded as a primary disease of bone whereas very often the involvement of bone

is but an incident of general septicemia. Radical surgical treatment, by which a bone was opened wide to locate a small focus, frequently resulted in spreading the disease, and death. Many years ago a young orthopedic surgeon boldly challenged his chief's radical methods by putting his patients in casts and at rest and, strangely enough, his results were excellent and fewer children died. Sad to say, however, it cost him his position on the staff of that hospital. Now it is generally recognized that in these cases surgical methods must be very conservative. If operation is carried out, provision should be made for wide drainage by a vaseline pack and fixation in a cast, according to the method of H. Winnett Orr of Lincoln, Nebraska. In chronic cases, the same method is used but it must be preceded by meticulous surgical care in that all sequestra, infected pockets and sinuses must be cleaned thoroughly.

Sulfonamides were introduced into this country about 1937 and since that time they have been used extensively for many conditions including osteomyelitis. Prontosil was the first drug in this line to be used in this country; then came sulfanilamide, sulfathiazole, sulfadiazine and others. Sulfanilamide is considered the most effective in the treatment of streptococcic infections while sulfathiazole is thought best for staphylococcic infections. These drugs are not particularly effective after suppuration has become extensive. Undoubtedly, however, many lives have been saved in those cases in which the blood cultures have been positive. Last winter, for the first time, I saw an adult patient recover from staphylococcic septicemia complicated by osteomyelitis of the femur. I am confident sulfathiazole saved his life.

Ununited Fractures.—Orthopedic surgeons are called on to treat ununited fractures. Frequently such fractures are compound and infection has taken place—the result of severe, crushing types of trauma. After long months of waiting for the infection to subside (frequently a year or more after all drainage has ceased) a bone grafting operation may be undertaken. Although the technical steps of the operation may be adequately carried out, the old infection may flare up and the work be lost. Sulfonamides have enabled us to perform these hazardous operations with a much lower rate of infection. Before operation, the patient is given the drug by mouth until the concentration of the drug in the blood is at the desired point; before the wound is closed at the completion of the operation the surface of all tissues is covered carefully with a thin layer of the sterilized, powdered drug that has been selected. After surgical operation, the concentration of the drug in the blood should be observed for at least a week to insure maintenance of an adequate concentration. Administration of these drugs is not without peril; patients with injured kidneys do not tolerate them well and, if the leukocyte count goes much below normal, administration of the drug should be discontinued. There is no doubt of their value in the treatment of infected wounds of all types but sound surgery should at all times be the master of the situation.

The Recent Past and the Future Need

Twenty-five years is a quarter of a century and during that span of time many changes occur and much progress is made. Other conditions in the field of orthopedic surgery have improved but they are too numerous to be mentioned at this time.

Social advances have been made in care of the crippled child but we are still found wanting in similar care of the adult. The handicapped person now has the opportunity of training for a line of work which will enable him to be self-supporting. Changes, as mentioned, occur in the type and frequency of certain diseases. What the world needs more than anything else at present is a type of mental hygiene which will sweep aside and segregate the evil-mindedness of such men as Hitler, Mussolini, Hirohito and their ilk. Only thus can be prevented such world catastrophes as we are now experiencing. Let us pray that the next twenty-five years will see this accomplished.

THE PROGRESS OF OBSTETRICS DURING THE PAST TWENTY-FIVE YEARS

W. A. COVENTRY, M.D.
Duluth, Minnesota

A REVIEW of the progress of obstetrics in Minnesota during the past twenty-five years is best revealed by the very marked decrease in maternal and fetal death rates during that period.

Thus it will be seen that Minnesota has for twenty-five years had a favorable maternal death rate as compared to the national rate. It also shows that the rate today is one of the lowest, if not the lowest, of any state in the Union.

MATERNAL DEATH RATE

Year	*Minnesota*	*U. S. Bureau Rate Average of All States*
1915	5.2	6.1
1920	6.2	8.0
1925	5.2	6.5
1930	5.4	6.7
1935	4.7	5.8
1940	2.2	3.7
1941	2.0	Not available

This most favorable report has not just happened. It is the result of many factors, largely brought about by, first, a program of education fostered by the Children's Bureau at Washington, by the efforts of the State Board of Health and our own teachers in the University of Minnesota, and last, but not least, by the untiring efforts of the obstetricians of this state who have campaigned in many and devious, but arduous ways, to make studies of the main causes of maternal deaths, and set out to teach and preach how these difficulties may be overcome.

The main causes of maternal death fall under four main headings: hemorrhage, sepsis, toxemias, and a miscellaneous group. In the prevention of hemorrhage, there has been less progress made than for any other cause, largely because there are so many extrinsic factors involved. The rate in Minnesota for maternal deaths from hemorrhage has not decreased, while from sepsis the rate has fallen from 1.8 in 1922 to 0.53 in 1940. In toxemic conditions, the rate fell from 1.10 per cent to 0.47 per cent in a corresponding period of time and in the group of miscellaneous causes, a decrease of 66 per cent is noted, showing a much better rate in Minnesota than in the United States at large.

Probably one of the greatest advances in maternity during the past twenty-five years has been the persistent stressing of and insistence on prenatal care, such prenatal care to begin as soon as possible after conception. So great have been the results from this campaign that now it is a rarity to find a pregnant patient who is not under the observation of a physician throughout her entire pregnancy and a rarity to find a physician in this state who does not insist on prenatal care for at least the essentials of a complete physical examination including a Wassermann and pelvic measurements followed by monthly or semimonthly examination of urine, blood pressure, blood, and the weight of the patient. Not only have these examinations been of inestimable value to the patient, but they have made the physician more alert and more eager to diagnose impending dangers of hemorrhage, malposition, toxemia, severe anemia, et cetera, which when early discovered make it possible to do much to avert impending trouble for mother and fetus.

Twenty-five years ago sepsis accounted for more maternal deaths than any other one cause. Now it is at the bottom of the list. The advent of the gloved hand, the disapproval of vaginal examination under any than the most careful aseptic technique, and the great increase in the number of hospitalized obstetrical patients, all have been a great help in lowering this rate. The advent of finger rectal examinations during the progress of labor makes it a rarity to do a vaginal during this stage of labor. The free use of soap and water has been a great help. Much has been done during the past twenty-five years toward the use of vaginal antiseptics. All types of germicides have been advocated and used. The relative merits of the various antiseptics leaves room for much discussion, but, in any event, it has taught the obstetrician to respect the possibilities of infection via the vaginal route.

I believe the lowered incidence of, and the education directed toward prevention and cure

From the Department of Surgery, Gynecology and Obstetrics, The Duluth Clinic, Duluth, Minnesota.

of venereal diseases during these twenty-five years has had much to do in the prevention of puerperal sepsis. A postpartum neisserian pelvic infection has almost disappeared from the picture.

Toxemic conditions have decreased 60 per cent during the past twenty-five years, as the result of much intensive investigation in the world's obstetrical centers and the teachings of our schools. Incorporated in the value of prenatal examinations is the early recognition and differentiation of nephritic conditions from true toxemic conditions and eclampsia, the interpretation of the value of urine tests, examination of eyegrounds, blood pressure levels, edema, and weight increases, especially in the later months of pregnancy, and the determination of avenues of treatment not only to save the baby, but also to prevent damage to the mother's kidneys, blood vessels and liver that might otherwise result in permanent insult to these organs. Although future investigations will undoubtedly clear up many of the theories now advanced as to the causes of toxemia, there is at present much to be learned for future generations.

This progress made in the lowering and prevention of maternal deaths has also had a most favorable effect on the lowering of the fetal death rate both stillborn and newborn.

It might be well to review a few of the new methods of treatment of the obstetrical patient that have come to stay or the old ones that have gone for good during the past twenty-five years. These remarks may have a personal slant, but take them for what you think they are worth.

1. In considering measures to alleviate pain during labor, the barbiturates should receive chief mention. Such a wave of enthusiasm, never, in my humble opinion, has entered the obstetrical field in a given time as in the era of barbiturates for the relief of labor pains or for "painless labor." The number of drugs and their method of use, their sane and insane use, the effects upon mother and newborn, the necessity for hospital care and nurses to properly supervise these medications—well, volumes have been written by all kinds of enthusiasts, and now I think we can see the near decline of the barbiturates in the management of the first stage of labor. There are still some "old-timers," and their number is increasing, who believe that small doses of morphine properly administered can give a patient better rest than any barbiturate. There will be a reversion to the age-old fact that our forbears took no drugs at all and soon after delivery forgot that there were labor pains. There was no exhaustive lay literature for them to read and give them the impression that labor was a painless effort. Old Dame Nature, I believe, did not intend it that way.

2. Cesarean section twenty-five years ago was considered a very major operation; it was done usually as a last resort and there was a resultant high mortality rate. The improvements in surgical technique, together with a desire for surgery, I believe, caused a wave of enthusiasm for cesarean section about ten years ago, wherein there arose in the minds of some good obstetricians too many indications for this operation which still has surgical dangers. It seems to me that with the advent of more diagnostic aids in x-ray pelvimetry, more skill in the diagnosis of placenta previa, that cesarean section gradually is finding its place in rational obstetrics. The types of low cesarean section that have been developed have certainly helped in lowering the morbidity and mortality rate from this operation.

3. There have been new types of anesthesia introduced within the past twenty-five years such as rectal, spinal and many new gas anesthesias and more recently, intravenous anesthesia. Many distinct advances have been made in the administration of anesthesia which have added much to the comfort of the patient in labor. The old, but yet very good, chloroform seems to have been relegated almost to the curiosities of the delivery room. I predict that soon some type of anesthesia easily administered, without harmful effect to the baby, but still very effective in relieving pain for the mother without retarding labor, will be found.

4. New techniques in x-ray pelvimetry have made great advances in the proper interpretation of pelvic measurements and the relationship of the fetal head to the pelvic inlet. There has also been a great advance in soft x-ray technique in determining the site of the placenta in the pregnant uterus.

5. Vitamins have a decided place in obstetrics, but the age in which we live with radio, advertising, propaganda and zealous enthusiasts have made for an easily led Mr. Public. We are on the wave now, and have been for the last five years; possibly we are on the crest of the wave—who can predict? Each for himself. My pre-

diction is that on the other side of the crest of this wave such a distinct recession will occur that Mr. Average Public will gasp for breath when he finds that the millenium was just a mirage.

6. The current and increasing use of episiotomy has been a great advance in obstetrical technique. It certainly eases the second stage, shortens labor, but most of all it protects the outlet of the vagina from many future cystoceles, rectoceles and prolapses and prevents many weakened perineums. Painstaking suturing and more accurate repair of incised or torn perineal parts have insured much in the way of permanent results. Perineal injuries and their end-results are becoming more uncommon in the gynecological field.

7. Better obstetrical teaching in our medical schools and the virtual insistence on delivery by natural methods, so firmly impressed in our own medical school, have relegated the high forceps operation to a thing of the past.

8. The technique of version as so ably taught by Dr. Irving Potter of Buffalo, New York, has been an epochal advance when version is indicated. True, we cannot believe the indications are so many as advocated by the master; still, the technique is masterful.

9. The development of the field of pediatrics within the past twenty-five years and its relationship with obstetrics has been of the greatest advantage in decreasing the newborn death rate and insuring much healthier babies.

10. Much has been learned within the past twenty-five years regarding the care of the mother postpartum. The value of movements and exercise in restoring the muscular tone of not only voluntary but involuntary muscles has made for a more rapid return to involution of all organs involved in the pregnant state. The papoose days may not be so far distant.

11. The value of postnatal examinations with office repair and correction of minor postpartum complaints is being stressed and is almost a final chapter in restoring our good patient to her normal self.

All this progress during the past twenty-five years has not just happened by a process of evolution. The efforts and interest put forth by Public Health Workers, as exemplified in the federal monies furnished the State of Minnesota through the State Board of Health and the University in conjunction with willing obstetricians, have made it possible to go out to certain centers in the state and to preach and teach better obstetrical care.

This interest among obstetricians has stimulated the formation of obstetrical societies such as the Central Association of Obstetricians—the organizers being leaders in our state in obstetrical matters; the progressives, who, not for gain but for mankind and womankind, have endeavored to learn more for themselves and to pass so freely their knowledge on to others. They have organized other "within the state" groups all for the same reason—to pass on to others their knowledge about the pregnant woman.

This great University of the State of Minnesota, through its teachers and more especially the Center for Continuation Study, by bringing all those interested in obstetrical knowledge under their roof, has added its mite to advancing obstetrical knowledge.

I have endeavored to avoid personal references but I can't resist the mentioning of Dr. Jennings C. Litzenberg, emeritus Professor of Obstetrics of the University of Minnesota, for his epochal teaching of conservative, sound and sane obstetrics and his many contributions to that field during the last twenty-five years.

All the aforementioned influences—desire for knowledge, free-will offerings of services, sound teachings—have their place. The State of Minnesota is among the states in the lowest brackets of the maternal death rate of the nation.

HANDS UNIMPORTANT IN SPREAD OF "FLU"

Discovery that the influenza viruses type A and type B die in a few minutes if put on human skin, such as the palm of the hand, and allowed to dry there, was announced by Commander Albert Paul Krueger, in command of Naval Laboratory Research Unit No. 1 at the University of California.

"Virus solutions so strong that a teaspoonful would kill half a billion mice lost all disease-producing capacity within 10 minutes," Commander Krueger, formerly professor of bacteriology at the university, stated.

"These results emphasize again the importance of tiny virus-containing droplets sprayed into the air when one sneezes, coughs or even talks vigorously, as a means of spreading influenza. Hand to hand distribution of the virus and eventual hand to mouth transfer would appear to be unimportant hazards."—*Science News Letter,* December 5, 1942.

ADVANCES IN RADIOLOGY IN THE PAST QUARTER-CENTURY

R. G. ALLISON, M.D.
Minneapolis, Minnesota

RADIOLOGY has advanced more rapidly than any other branch of medicine in the past twenty-five years. This advancement first occurred in revolutionary changes in apparatus. Once these improved machines and materials were available, diagnoses began to improve by leaps and bounds.

There are perhaps two reasons for this rapid advancement which began at the time of World War I. First, the specialty itself was relatively young, but most important was the necessity for new, easily transportable and efficient x-ray apparatus for our troops in France. One has only to reflect on the gas tubes, glass plates, mechanical rectification and even mercury interruptors commonly in use at that time. War called for more efficient apparatus, and the inventors and manufacturers responded in a manner that gave us more improvements during the year 1917 than had been made in all the years since Roentgen announced his discovery.

Dr. W. D. Coolidge, who in 1912 developed the x-ray tube which bears his name, in 1917 developed a self-rectifying tube. This contribution of his made it possible for the manufacturers to develop a compact portable machine to energize this tube. This made bedside x-ray work possible and made it practical to treat fractures successfully by skeletal traction without moving the patient to obtain plates. The manufacturers utilizing this self-rectifying tube were able to construct a similar x-ray for use in the field hospitals, the source of the current being a self-contained gasoline engine. Those two types of machines did 90 per cent of the x-ray work done in the American Expeditionary Forces.

The Eastman Company, in this same summer of 1917, developed an extremely satisfactory x-ray film which gave beautiful detail, was easy to transport, develop and store, and could be transported with the wounded soldiers and their records without danger of breakage.

A few years after the World War, Dr. Hollis E. Potter of Chicago perfected the movable grid which bears his name and the name of the original inventor, Dr. Gustav Bucky. This apparatus enabled the radiologist to obtain radiographs showing beautiful detail in areas previously inaccessible owing to the secondary radiation set up in the body of the patient with consequent blurring of detail. This apparatus was the second great invention since Roentgen's time, the first being the Coolidge tube. While all of these machines and apparatus have been further improved upon, they stand today as the basis upon which all subsequent apparatus has been modeled.

The next basic invention was the planograph developed a few years ago. This apparatus, as you know, was developed in order to enable the radiologist to go after one particular area of the body and obliterate all other detail on the plate. Thus it is possible with this apparatus to show perfect detail of the sternum without the superimposed shadow of the spine, ribs and lungs. Any given portion of a vertebra can be shown without superimposed shadows of other portions of the same vertebra. Laryngeal cords and tumors can be clearly delineated. It is applicable to every portion of the body. So far its greatest value has been in diseases of the chest. Here the absence or presence of pulmonary cavity or tumor may be clearly shown even in the presence of large pleural effusions or in chronically thickened pleura which on the ordinary chest film would obscure detail of any underlying stricture.

This method is still not widely used and will not be until the end of this present war enables the manufacturers to further perfect it. However, many radiologists with the use of "homemade" apparatus have done excellent work by employing this method.

Having now mentioned these basic inventions in apparatus developed in the past twenty-five years, let us consider some of the chemical and physical media which have been brought forth as diagnostic aids and agents in the same period of time.

Dandy of Johns Hopkins, in 1918, developed ventriculography. This has done much to clarify the diagnosis of intracranial new growths as well as to help to differentiate them from the early and late effects of traumatic lesions.

Forestier of France, in 1922, developed lipiodol. This oil can be safely introduced into the bron-

chi, the uterus, the nasal accessory sinuses, and the spinal canal. The diagnosis of pathological conditions in these areas has been made infinitely easier and more accurate by the use of this oil. It is the only method by which prolapsed inter-vertebral disc can be visualized and localized. After the diagnosis has been made the oil can then all be withdrawn through the same needle through which it was introduced.

Cole and Graham of St. Louis, in 1924, developed a gall-bladder dye which has made the diagnosis of pathologically functioning gall bladders, with or without stones, extremely accurate.

Swick, in 1928, developed an intravenous kidney dye which has proven to be an outstanding agent in the diagnosis of injuries and diseases of the urinary system. By the use of this method the urologist has been able to avoid much cystoscopy. He has further been able to obtain much information not obtainable by retrograde pyelograms. This method is invaluable in the diagnosis of hydronephrosis. By its use non-opaque stones can be recognized with a high degree of accuracy. Opaque stones can be localized and differentiated from other conditions casting similar shadows on the routine plate. Used in connection with cystoscopy and retrograde pyelograms it should leave few diseases of the urinary tract undiagnosed. It is by far the most valuable and often the only method of recognizing some of the congenital abnormalities of the urinary tract.

Diseases of the Chest

Although as early as 1906 Williams of Boston had written extensively on the fluoroscopic diagnosis of cardiac and pulmonary lesions, his work attracted little attention.

Lewis Gregory Cole of New York City had, as early as 1907, made a plea for the use of x-ray plates in the diagnosis of tuberculosis. Again, in 1910, he classified the changes produced by pulmonary tuberculosis on the x-ray plates. His information had been obtained in the morgue at Bellevue Hospital. Here he radiographed hundreds of chests post mortem and correlated his findings on the plate with the autopsy findings.

In 1911, Kenyon Dunham of Cincinnati carried the work of Cole still further with serial microscopic section studies of both normal and pathological lungs. Dr. Cole and Dr. Dunham, by 1912, had interested the Saranac Lake men in the x-ray diagnosis of chest conditions. It was my privilege to enter on my two-year service in 1912 simultaneously with the advent of their first x-ray machine. Even the enthusiasm of the Saranac staff made little impression upon the world at large. Many inquiring workers, however, came to Saranac in those early years between 1912 and 1917 and became converts to the x-ray method of diagnosis.

When World War I began for us in 1917, Dr. Cole and Dr. Lawrason Brown made many futile attempts to interest the Surgeon General's office in obtaining a single chest plate of each army recruit. When this was refused they obtained funds from the health department of New York State and made stereoscopic plates of a National Guard Regiment in New York City. They found 10 per cent of the 2,000 men examined to have definite parenchymal tuberculosis. Even with these published facts the Surgeon General's office refused to do anything further in regard to x-raying the chests of recruits. I might add, however, that the Surgeon General's office was guided in their decision by the advice of both civilian radiologists and civilian internists who still felt the method was without value. It was not until the several hundred young radiologists who were trained in the army School of Radiology began to make their influence felt that the x-ray diagnosis of tuberculosis began to be generally accepted. The influenza epidemic of 1918 furnished a fruitful field for their endeavors. The portable bedside x-ray machine invented that year made routine plates easy to obtain. The radiologists found ardent allies in the pathologists during this epidemic and gradually the value of this method began to be forced down the throats of the ward surgeons and physicians. When the war ended the x-ray diagnosis of tuberculosis was at last firmly established twelve years after Cole had written his first article on the subject based on a comparison of post mortem x-ray findings as compared with autopsy findings.

I regret that Lawrason Brown did not live to see his stand in 1917 vindicated. It must be a source of satisfaction to Dr. Cole to see his recommendation to the Surgeon General of the army accepted in full twenty-five years later.

The late Willis Manges of Philadelphia, in 1922, made a classic observation in his description of the x-ray findings in non-opaque foreign bodies in the air passages. He found that non-opaque foreign bodies produced either obstructive emphysema or atelectasis on the affected

side. This is particularly well shown on plates made in different phases of respiration. As a result of Manges' work it became immediately apparent that primary bronchial carcinoma gave identical findings and thus early primary new growths of the lung began to be recognized.

Bone Pathology and Injury

Much good work had been done on the x-ray diagnosis of bone diseases prior to 1917, chiefly by German workers, notably Alban Koehler.

It was not until 1921 that an excellent English text appeared on the subject. In that year, Dr. F. H. Baetjer and Dr. C. A. Waters of the Department of Radiology of Johns Hopkins University published their textbook entitled "Diseases and Injuries of the Bones and Joints." This text, written primarily for the medical student, was of far greater aid to most radiologists than its modest authors would admit. It remained the standard work in this country until the English edition of Koehler's work appeared in 1929. Baetjer and Waters were, however, the pathfinders in the diagnosis of bone diseases. The basic principles brought out by them furnished the ground work for all the work which has since been done in bone pathology.

Gastro-Intestinal Tract

The x-ray diagnosis of diseases of the gastro-intestinal tract was resting on a sound foundation prior to 1917. Most of the pathologic conditions encountered therein had been described before that time.

Akerlund, in 1921, published his work on duodenal ulcer. He was the first to call attention to the visualization of an ulcer crater on the posterior wall of the cap, and visible only when localized pressure was applied over the cap during the fluoroscopic and plate examination.

Lawrason Brown and Homer Sampson of Saranac Lake, in 1926, published a monograph on intestinal tuberculosis and accurately described the x-ray findings in both the hypertrophic and ulcerative types of this disease.

X-Ray Treatment

The x-ray was employed in the treatment of diseases of the skin within a year after the Roentgen discovery. Pusey of Chicago and Caldwell of New York published a small treatise on the subject in 1898.

Little progress, however, was made in x-ray treatment until the period immediately following the World War. Coolidge at that time developed an x-ray tube capable of handling 200,000 volts and the manufacturers immediately responded with a machine capable of furnishing the current. Since that time both tubes and machines capable of delivering voltages in excess of two million volts have been developed.

Used alone or in combination with radium in selected cases, treatment at higher voltages has done much to reduce the mortality in certain forms of malignant new growths. It has also been a remarkable palliative agent in skeletal metastases. Many conditions, however, do not need these higher voltages. It should be borne in mind always that superficial growths as well as all growths extremely susceptible to radiation should be treated with the lower voltages rather than the higher. The reason for this is the obvious damage done to the normal surrounding tissues. This is best shown by the tremendous increase in pulmonary atrophy or radiation fibrosis of the lungs which developed following the use of higher voltages in the treatment of carcinoma of the breast.

In deepseated abdominal new growths, however, the higher voltages have a very definite advantage. Judiciously used in combination with radium this treatment has resulted in a remarkably higher incidence of cures in carcinoma of the cervix of the uterus. Postoperative radiation in carcinoma of the breast has considerably increased the incidence of five- and ten-year cures when compared with the non-radiated cases.

The reader should bear in mind that the writer has of necessity not been able because of lack of space to give any detailed account of much of the valuable work which has been done by hundreds of capable men during the past twenty-five years. It has only been possible to mention epoch-making discoveries in apparatus and media, in addition to the few outstanding diagnostic procedures which have had the greatest influence in the widespread use of this still comparatively young specialty.

Malaria is not confined to the tropics; in 1937 there were 4,000,000 cases in the United States.

PRIMARY BRONCHIOGENIC CARCINOMA

Report of a Five-Year Surgical Cure

THOS. J. KINSELLA, M.D.

Clinical Assistant, Professor of Surgery, University of Minnesota Medical School
Minneapolis, Minnesota

PRIMARY bronchiogenic carcinoma, in spite of its relative frequency, is probably less well understood than most conditions encountered by the physician in general practice. Much of this occurs because the average physician is quite unfamiliar with the disease as seen clinically, the rest because of the varied picture which the condition itself may present. It is, without doubt, the most notorious masquerader with which we are commonly called upon to contend.

This condition, in the mind of the average physician, is considered a rare one which need not be constantly kept in mind. Such, however, is not the case. It is found in at least 1 per cent of all postmortem examinations, and thus cannot be considered a rare condition. It constitutes from 12 to 15 per cent of all carcinomas encountered at autopsy, and is of the same approximate order of frequency as carcinoma of the uterus and carcinoma of the rectum. The apparent, marked increase in frequency observed clinically can easily be explained by a better appreciation of the clinical picture, while the increase noted in postmortem series may be offset to a considerable degree by a recognition of the fact that numerous cases previously diagnosed as sarcoma of the mediastinum, endothelioma of the pleura, sarcoma of the lung and carcinoma, primary site undetermined, were in reality cases of primary bronchiogenic carcinoma with metastases.

Primary cancer of the lung begins as a malignant pathological process in the wall of one of the bronchi, hence the accepted name primary bronchiogenic carcinoma. Microscopically it may appear as a fairly well differentiated glandular type of structure, adenocarcinoma, as a fairly well differentiated epithelial structure, squamous cell carcinoma, or more commonly as a more rapidly growing undifferentiated mass, now referred to as undifferentiated carcinoma, formerly called an oat-cell tumor or even a sarcoma of the lung. It may begin towards the periphery of the lung but is more commonly recognized in the larger bronchial radicals. The growth may develop relatively slowly or very rapidly, depending upon the type and degree of differentiation of the tumor itself. This, however, need not be consistent as in some tumors certain areas may be found showing well differentiated adenocarcinoma, others well differentiated squamous cell carcinoma, and still others a wildly growing undifferentiated tumor.

All types of these tumors tend to metastasize, some sooner than others, but all relatively early, and frequently very extensively. Metastases occur frequently along the lymphatics underneath the bronchial mucosa where the tumor may infiltrate to a considerable distance beyond the original site. The regional and mediastinal nodes soon become involved. A few extend peripherally to involve the pleura and chest wall early. The liver is the next most frequent site and is commonly involved, often so extensively that the primary tumor is dwarfed, and an abdominal primary tumor is sought. Widespread metastases throughout the body are frequently seen, with involvement of the brain, the osseous system, the adrenal, kidney, pancreas, thyroid, spleen, cardiac muscle, skin and almost any other structure. Such metastases may so completely overshadow the small primary tumor that it is missed, not only clinically, but even at pathological examination unless a careful search is made.

The frequency of brain metastases in primary bronchiogenic carcinoma is well recognized by the neurological surgeons, who on numerous occasions in the past have explored what were apparently primary cerebral tumors only to find that they were metastatic from a small unrecognized primary in the lung. The metastatic deposits in thyroid, adrenal, kidney and pancreas have at times been mistaken for the primary site of the malignant process and undoubtedly in the past have led to considerable confusion as to the relative frequency of bronchiogenic carcinoma. The pathological course and progress of the condition is so extremely varied that it naturally may be expected to produce a very bizarre clinical picture.

Clinically, as with other carcinoma, this pri-

mary tumor of the lung is essentially a disease of the latter half of life, occurring most frequently in the fifth, sixth and seventh decades, although it has been reported in almost every year of life, from a few months of age to the nineties. It must, however, be given most serious consideration in differential diagnosis in patients beyond the age of forty. It occurs four times as commonly in males as in females, a consideration which may be given some weight in making a differential diagnosis in the female patient.

There is, perhaps, no pathological condition which so frequently and efficiently masquerades as some other process. The clinical picture of pneumonia, pulmonary tuberculosis, virus pneumonia, lung abscess, bronchiectasis, empyema and metastatic tumor in the lung may all be simulated by primary carcinoma, or may even be associated with it. An exceedingly careful clinical study may be required to establish the true diagnosis. Probably the most difficult differential diagnosis is that involving a process in the upper portion of the lung with some atelectasis present where tuberculosis and carcinoma must be distinguished, as this is an area where both conditions are frequently encountered. Atelectasis may occur in both, while cough and expectoration, fever, wheezing, blood streaked sputum, tightness in the chest or pleurisy, loss of weight, anemia, and loss of a sense of well-being may occur with either one. The finding of tubercle bacilli in the sputum, of course, would establish the one diagnosis, yet numerous cases of pulmonary tuberculosis with atelectasis do not show a positive sputum at all times because of the bronchial obstruction present.

The occurrence of cavitation within the involved area which ordinarily would suggest tuberculosis may not absolutely indicate it because bronchiectatic cavitations may occur distal to the obstructing mass of a bronchiogenic carcinoma. Bronchoscopic examination, which in other localities of the lung is of extreme value, here may reveal no information whatsoever, as the upper lobe bronchus except for its orifice cannot be visualized through the bronchoscope, and nothing may be available for biopsy examination. Cutaneous tests, cultures, smears, and blocked sputum specimens, iodized oil bronchograms and all other available means may be exhausted and yet no positive proof of the diagnosis established. The case forming the basis for this report is an excellent example of this problem. In other instances, the finding of a positive sputum does not rule out carcinoma as the two conditions may coexist, and it is only the alert clinician who will be able to make the complete diagnosis.

The x-ray picture of bronchiogenic carcinoma is frequently considered a pneumonia until the process fails to clear. The same difficulty to a greater degree may be encountered in the so-called virus pneumonia where the picture may simulate a bronchiogenic carcinoma and where delayed resolution is common and will excite less concern than in an ordinary pneumonia. It is well recognized clinically that lung abscess and bronchiectasis may develop distal to any bronchial obstruction, and as bronchiogenic carcinoma so commonly gives partial or complete bronchial obstruction, it is not surprising that an associated lung abscess or bronchiestasis is observed quite frequently, particularly in the slower growing tumors. Add to this the fact that certain malignant bronchial tumors undergo central degeneration with abscess formation and we add another element of confusion. It is common knowledge that 10 per cent of the chronic lung abscesses occur distal to an obstructing bronchial tumor. In older people a lung abscess is quite likely to represent a degenerating carcinoma.

Certain bronchial tumors extend peripherally and involve the pleura, inducing pleurisy or a pleural effusion, either clear, bloody or purulent. The differential diagnosis between carcinoma and tuberculosis with a clear or bloody effusion is not always readily made. In the presence of a purulent effusion the finding of any type of organism in the pus does not rule out carcinoma as secondary inflammatory disease may complicate the picture and lead to an empyema. The recognition of tumor cells in direct or blocked sediments of pleural fluid is not always as simple as it might seem, and unless the pathologist has had considerable experience in such examinations it is likely to lead to errors in both directions.

Metastatic tumors to the lung from other sources may simulate bronchiogenic carcinoma, and conversely bronchiogenic carcinoma may simulate or produce metastatic lesions in the lung fields and elsewhere and lead to error in diagnosis. Some tumors, notably hypernephroma and carcinoma of the colon, have been reported as metastasizing to the bronchial mucosa producing an obstructing lesion which could be visualized

through the bronchoscope and at times recognized by biopsy specimens thus obtained. The clinical picture encountered then may be very bizarre, and a great deal of thought and study and numerous examinations required before the true diagnosis is established.

The clinical picture presented by bronchiogenic carcinoma can probably be understood better if consideration is first given to the development and progress of the local lesion. Bronchiogenic carcinoma apparently begins as an isolated neoplastic node in the wall of a bronchus of small, medium, or large calibre. As the mass develops it encroaches upon the lumen of the bronchus, interfering with the passage of air through this area, exciting some secretion and some local irritation, which may produce a slight cough, oftentimes dry, but possibly producing a small amount of clear, mucoid sputum. If ulceration occurs on the surface of the growth, or if coughing is severe, blood streaks or even a small amount of blood may be expectorated. As the growth increases in size filling the bronchial lumen, and it takes only a smaller tumor to do this, even in the larger bronchi, it produces some interference with the passage of air by this point. If this obstruction is partial and permits the entrance of air, but not its exit, there will develop in the lung distal to the tumor an obstructive emphysema which if small will give no clinical findings, but which if large may be detected on physical examination as an area of normal to hyperresonant percussion note, with distant breath sounds and probably no rales, and on x-ray as a local area of increased translucency of the lung.

If the obstruction becomes more complete and air can neither enter nor leave the involved area of the lung, the air trapped distal to the mass absorbs rather rapidly producing an atelectasis of this portion of the lung which again if small cannot be found clinically but which if larger may be recognized by an area of altered percussion note, from impairment to dullness, with distant to absent breath sounds early, later replaced by the increased transmission of solidified lung. There are usually no rales present, though if the obstruction is slightly intermittent or is altered by deep breathing or cough, a wheeze or squeak may at times be heard. Clinically there is a sensation of tightness in the chest in the involved area, at times interpreted as slight pleural pain. Roentgenograms show an area of increased density in the lung field usually of homogeneous consistency with displacement of the heart, mediastinum or diaphragm to the involved side, if the area involved is large.

The patient by this time may have noticed a slight wheeze or clicking sensation in the involved area, particularly after cough, on exertion, or upon taking a deep breath, and may have experienced a gradual loss of strength, a sense of fatigue, or may have become somewhat anemic depending upon the amount of cachexia associated with the local growth. As the tumor continues to grow there is frequently increasing cough with expectoration of nonpurulent sputum, at times blood streaked, occasionally true pleural pain, a slight sense of breathlessness even without exertion, or even an inability to take a deep breath. If secondary infection now enters into the picture in that portion of the lung distal to the obstruction there may be a change in the character of the sputum which may take on the character of that of a bronchitis or bronchiectasis, or even become foul if abscess develops. Fever in varying degree may appear. Ulceration of the local growth may produce frequent bleeding, usually not large in amount, though rarely it may be so. If pleural involvement occurs a pleural effusion may develop following an acute attack of pleurisy and increasing dyspnea result from the accumulation of fluid in the pleural cavity.

The progress from the original state to this stage may be a matter of days, weeks or even months depending upon the rapidity of growth of the tumor and the amount of obstruction produced. By this time usually the patient has sought medical advice and may have received considerable treatment under a variety of diagnoses. Primary bronchiogenic carcinoma may be considered, though it frequently has not been given any consideration up to this time. As the disease progresses all symptoms may become more marked. The patient may now begin to complain of symptoms resulting from secondary involvement of other structures, such as pain from involvement of the pleura, chest wall or ribs, or difficulty in breathing from the involvement of the bronchial nodes; difficulty in swallowing from encroachment of such nodes upon the esophagus, or breathlessness from interruption of the phrenic nerve by tumor tissue in the mediastinum or by increasing pleural effusion; pain in the shoulder girdle or tro-

phy of the muscles about the shoulder girdle from direct involvement of the upper ribs, vertebral bodies or brachial plexus as occurs at times in apical carcinoma; eye symptoms from interruption of the sympathetic trunk; headaches, nausea and vomiting and all of the findings of a primary brain tumor from cerebral metastases; backache and abdominal pain from involvement of the retroperitoneal nodes and the liver, or local symptoms referrable to almost any site invaded by the tumor.

Secondary infection in the lung about the tumor may change the whole picture to one characteristic only of lung abscess or bronchiectasis, or if in the pleural cavity to that of an ordinary empyema. From a diagnostic standpoint these latter considerations are of interest and must be taken into account, but from a therapeutic standpoint they all develop because of the spread of the disease from the original local site and are indications of disease which has progressed beyond the stage where clinical cure can be obtained by any means. Our clinical goal must be the diagnosis of the disease before it has reached this stage if we hope to offer more than palliative treatment to the patient.

Diagnosis

Probably one of the most important factors in establishing a diagnosis of primary bronchiogenic carcinoma lies in keeping the condition always in mind and looking for it under any and all circumstances. It is most frequently overlooked because it is not considered in the differential diagnosis. In general, any patient over forty, particularly a male, who develops unexplained, persistent cough, expectoration, blood spitting, wheezing, breathlessness, tightness in the chest, pleurisy or pleurisy with effusion, asthma, "chronic bronchitis," should be suspected of possible bronchial involvement. Added to this group should be all patients presenting unresolved or slowly resolving pneumonias, atelectasis, localized emphysema, and all other peculiar or unusual shadows on x-ray, particularly in the older group, but including some in all age groups. The findings of a local emphysema or atelectasis, or a localized persistent wheeze on physical examination should arouse suspicion of a bronchial obstruction, possibly from tumor.

Sputum studies to relatively rule out tuberculosis should always be made, following which sputum, particularly particles which might resemble tissue, should be embedded, and sectioned for microscopic examination for tumor cells. Similar studies should be carried out on pleural fluid. Roentgenograms of the chest, and good iodized oil bronchograms should then be made. No examination is complete without a thorough bronchoscopic examination with biopsy of suspicious areas. In upper lobe lesions with atelectasis where nothing can be seen on bronchoscopic examination, it may be wise to establish an artificial pneumothorax on the affected side with the idea of pushing the upper lobe down and changing the angle of the upper lobe bronchus so that it may more readily be visualized. In certain instances, following the establishment of pneumothorax, pleuroscopy may be indicated if pleural metastases are suspected. This procedure may at times save the individual an unnecessary exploratory thoracotomy.

When all other methods of conclusively establishing the diagnosis have failed and there is still a strong probability of bronchiogenic carcinoma or one cannot be certain whether the lesion is operable or not, even when clinically proven, exploratory thoracotomy is indicated. At times this will reveal ample evidence of the presence of a bronchiogenic carcinoma which can then be adequately treated surgically at the time. It was by finally resorting to this method that the present five-year cure was accomplished.

Once the diagnosis has been established and surgery is being considered, thorough studies must be made to rule out metastases in all possible locations. The establishment of a pneumoperitoneum, followed by roentgenograms of the liver region for irregularities may at times reveal liver metastases. Peritoneoscopy with direct visualization of the surface of the liver may demonstrate liver metastases which, of course, would indicate a hopeless, inoperable condition.

Treatment

The fundamental considerations in the treatment of primary bronchiogenic carcinoma are the same as those of carcinoma elsewhere in the body, namely, early diagnosis and the complete eradication of the tumor-bearing organ and its regional lymphatics before the disease has spread from its local site of origin. This, in primary bronchiogenic carcinoma, means a total pneumonectomy by primary dissection within the mediastinum, with removal of the regional lymph nodes which drain the affected lung. Lobectomy

or pneumonectomy by tourniquet method should be regarded as incomplete operations and considered as analagous to simple amputation of the breast for carcinoma. If the condition is inoperable as proven by preliminary studies or at exploratory thoracotomy, which must be resorted to quite frequently, then palliative treatment by radiation therapy may be indicated and may at times afford considerable relief. It is not, however, to be considered as curative as no convincing cured cases have been reported by this method. For the relief of dyspnea, cough, wheezing, chest pain or certain obstructive symptoms considerable may at times be accomplished by it.

Criteria of Operability

Once the diagnosis of primary bronchiogenic carcinoma has been established the whole situation should be reviewed as to the possibilities of surgical intervention. The following may be presented as criteria of possible operability.

1. Absence of metastases both local and distant, especially in the lung, pleura, mediastinum, liver and brain.

2. The absence of nerve or bone involvement, particularly of the phrenic, recurrent laryngeal or sympathetic trunks, and the ribs adjacent to the tumor.

3. The absence of pleural fluid, even if carcinoma cells cannot be demonstrated in it.

4. The absence of involvement in the trachea and proximal centimeter of the main bronchus on the affected side.

5. The absence of rigidity of the trachea or bronchi on the affected side, suggestive of peribronchial infiltration or nodal involvement.

6. The absence of cardiac, renal or other serious constitutional disease.

7. The general physique must be sufficiently robust to offer a legitimate chance of withstanding the radical operation necessary.

8. The age group and expectancy must be such as to justify the radical surgery.

Contrariwise, the following may be considered as absolute criteria of inoperability:

1. Distant metastases of any type.

2. Large mediastinal mass.

3. Evidence of interruption of the phrenic, sympathetic or recurrent laryngeal nerve from direct infiltration by advancing tumor.

4. Cervical or axillary nodes positive to biopsy.

5. Involvement of the trachea or primary bronchus immediately adjacent to it by tumor tissue.

6. Evidence of pleural involvement with demonstrable masses, the finding of malignant cells in pleural fluid, and possibly even the presence of pleural fluid alone.

7. Age, marked debility, coronary heart disease, or other serious lesion indicating a limited expectancy.

If the conditions first outlined can be met, or at least tentatively met, we then feel justified in recommending an exploratory thoracotomy, planning upon radical surgery if local conditions prove favorable. At operation, local conditions may be found which render the condition inoperable, such as lymph node involvement beyond the primary nodes, direct infiltration of the chest wall, invasion or fixation of tissues within the mediastinum. The finding of isolated lymph nodes in the mediastinum *per se* may not indicate that the condition itself is inoperable, because associated secondary infection in the lung may give rise to a nonmalignant lymphadenitis.

From the surgical standpoint primary bronchiogenic carcinoma presents some of the same surgical possibilities for cure as does carcinoma of certain other accessible localities, such as the breast, stomach and colon, where there is a blood supply which can be controlled and a primary lymphatic drainage system which can be excised with the tumor and surrounding tissues. The surgical possibilities of such a condition have been recognized for a considerable period of time, but it is only within the last ten years, with the modern developments in thoracic surgery and anesthesia that the condition has been successfully treated surgically.

Resection of the lung may be carried out either through an anterior or a posterior thoracic incision depending upon the surgeon's preference. Both afford adequate exposure and access to the hilum of the lung for primary ligation of the vessels, primary section and suture of the bronchus and a primary excision of the regional lymphatic nodes. If conditions warrant, the procedure may be carried out in two stages, the first including a dissection of the hilar structures up to and including ligation of the pulmonary artery, for the lung will survive following its ligation if there is no interference with the venous return. The second stage of the extirpation may be carried out at a subsequent date. Pneumo-

nectomy by mass ligation, lobectomy by either mass ligation or primary dissection must be considered as inadequate operations for they do not fulfill the primary principles recognized as adequate for the successful treatment of malignant disease.

Case Report

Mr. A.I.B., sixty-two years of age, a hotel keeper and former railroad conductor, was admitted to the Northwestern Hospital on July 7, 1937. He first consulted me on June 21, 1937, on the advice of Dr. E. E. Carpenter of Superior, Wisconsin, because of cough, fever and loss of weight. He had apparently been perfectly well until the middle of December, 1936, when he developed an acute tonsillitis followed by a severe arthritis of his right great toe which persisted for two weeks. With the tonsillitis he developed a fever of 101 degrees Fahrenheit with cough and expectoration of a clear mucoid material, 15 cubic centimeters in amount in twenty-four hours. After the acute process had subsided, however, cough and expectoration of clear mucus with some dyspnea without wheezing persisted. Physical examination and fluoroscopic examination on January 20, 1937, were reported as negative. He gradually lost in weight and strength. An x-ray picture of his chest in April was interpreted as showing an unresolved pneumonia.

He remained in a rest home for a few weeks until his admission to the Middle River Sanatorium on May 26, with a tentative diagnosis of pulmonary tuberculosis. All studies in the sanatorium, including many examinations of sputum and guinea pig inoculations, were negative for tuberculosis. The possibility of bronchiogenic carcinoma was considered and he was referred to Minneapolis for further studies. During this period of time he had lost weight from 217 to 178 pounds, but had regained 7 pounds during his residence in the sanatorium. His cough and expectoration had continued but the dyspnea had disappeared with bed rest. There had been no wheezing at any time. For a period of about ten days there had been slight discomfort in the left anterior chest which disappeared under symptomatic treatment. Aside from a persistent fever of 99 to 100 he had no symptoms of note.

Physical examination revealed a large, well-developed, well-nourished, adult male, 5 feet 9¾ inches tall, weighing 185 pounds, with evidence of recent weight loss. His blood pressure was 120/70, pulse 82, temperature 98.4, respiration 18. The head, eyes, ears, nose and throat were normal. There were no enlarged lymph nodes. The thyroid gland was normal. The heart was normal. The blood vessels were soft. The right side of the chest was negative to physical examination except for an occasional sibilant rhonchus on deep inspiration in the inner second interspace, probably transmitted. The left side of the chest showed a normal percussion note with breath sounds very distant over the upper lobe. Whispered voice, spoken voice and tactile fremitus were diminished over the upper lobe, with a sibilant rhonchus on deep inspiration in the upper half of the chest. There were no rales to be heard after cough. The left diaphragm was slightly elevated but not paralyzed. The abdomen was normal, the liver not palpable, and no masses present. The genitals were normal. Rectal examination was negative. The reflexes were normal.

Laboratory Findings: Hemoglobin, 11.2 grams; erythrocytes, 3,911,000; leukocytes, 11,300; polymorphonuclears, 74.5 per cent; lymphocytes, 16 per cent; large mononuclears, 3.5 per cent; eosinophiles, 5 per cent.

The blood Wassermann was negative. The urine was normal. The electrocardiogram was normal. The sputum was negative for tubercle bacilli, and no tumor cells could be found.

Radiograph of the chest showed the heart and aorta shadows normal in size, shape and position. The right lung was normal, right diaphragm free. The left side of the chest showed a homogeneous density extending out from the hilar region in the upper portion of the chest which had increased considerably since the previous examination in May of 1937. This represented a localized atelectasis with some secondary emphysema in the upper lobe. The left diaphragm was slightly elevated.

A radiograph of the chest made after the establishment of a diagnostic left pneumothorax showed the right lung to be clear with a density extending out from the left hilum which was definitely in the left upper lobe. Conclusion: Bronchiogenic carcinoma with atelectasis and emphysema of the left upper lobe; normal right lung.

X-ray examination after the ingestion of barium revealed a normal stomach and cap, a normal distribution of the meal at the end of six hours, and a normal colon. There was an extensive hypertrophic arthritis of the lumbar spine.

Bronchoscopic examination performed by Dr. L. R. Boies on July 8, 1937, was reported as follows: The tracheal mucosa appeared to be normal. The carina was not thickened or injected. The openings of the right lower, middle and upper lobe bronchi were normal. In the left main bronchus there was an excessive amount of secretion. The mucosa of the left main bronchus was definitely injected and thickened, but there was no granulation nor points that bled easily. The lumen of the secondary trunks contained purulent secretion which was aspirated. There seemed to be some edema about the orifices of these secondary bronchi, with no evidence of any tissue suggesting malignant disease.

After the establishment of a left artificial pneumothorax another bronchoscopy was performed by Dr. Boies who reported as follows: The right side was negative. The left main bronchus contained a moderate amount of mucopurulent secretion. The bronchus to the left upper lobe appeared to have sagged down moderately as if it were compressed. No tumor or granuloma could be seen. The bronchus to the upper lobe could not be explored.

Although after extensive study we could not visualize a bronchiogenic carcinoma we were convinced clinically and by the x-ray picture that this condition did exist.

After discussing the whole picture with the patient and the family an exploratory thoracotomy was recommended.

Operation: Left total pneumonectomy (Reinhof technique). On July 20, 1937, under intratracheal cyclopropane anesthesia administered by Dr. Ralph T. Knight the left side of the thorax was opened through a curved anterior incision over the third interspace, with section of the cartilage above and below. There was an extensive pneumothorax present. The mediastinum was quite stable. There were extensive adhesions along a linear line at the level of the third rib anteriorly for a distance of about 12 centimeters. The upper lobe was adherent to the mediastinum above the hilum and to the lower lobe along the interlobar fissure. The upper lobe showed an obstructive emphysema, the lobe collapsing very little even under pressure, interfering considerably with our exposure. The lower portion of the upper lobe showed a hard nodule in the periphery with considerable induration throughout the lower half. The lobe, however, was mildly crepitant throughout, with a marked anthracosis present. The lower lobe was apparently normal. The hilar structures were not indurated; there were no large nodes present. There was no free fluid or tumor mass in the pleural cavity.

After the mediastinal pleura was opened, three enlarged lymph nodes were encountered, two above the pulmonary artery and one below the inferior pulmonary vein. These were dark and soft and were excised and sent to the laboratory for examination and reported as negative for tumor.

The pulmonary artery was freed by blunt dissection, doubly ligated with No. 2 chromic catgut, transfixed and again doubly ligated with braided silk and then sectioned. The superior and inferior pulmonary veins were treated in like manner. The main bronchus was then dissected free, cut across about a centimeter from the carina, slit for a short distance transversely to weaken the cartilages and then closed with two layers of interrupted silk sutures. All lymph nodes encountered locally were excised. The posterior flap of mediastinal pleura was then tacked over the bronchial stump and the rest of the mediastinal defect closed with continuous silk suture. The chest wall was then closed without drainage, resuturing the divided cartilages and approximating the ribs by pericostal sutures, closing the intercostal muscles with continuous catgut and tacking the pectoralis muscle down over the incision to give an air-tight closure. The skin was closed by a lock stitch of dermal suture and then sealed with mastisol.

The patient tolerated the operative procedure very well, and while on the table was given 1000 c.c. of citrated blood, 2500 c.c. of normal saline and 500 c.c. of 5 per cent dextrose. The highest blood pressure recorded was 160/84, the lowest 96/64. The highest pulse rate was 96, the lowest 72. The highest respiratory rate 24, lowest 16. At the close of the operation his blood pressure was 124/80, pulse 84, respiration 20. He returned to his bed in good condition and was immediately placed in an oxygen tent where he remained for thirty-six hours when he decided he wished it discontinued. His condition remained satisfactory. He had considerable thick mucus in his throat which gave him a moderate amount of cough from which he developed considerable subcutaneous emphysema over the left side of his chest. Blood pressure, pulse and temperature were good, and the respiration slow except when disturbed by cough. There was no cyanosis present. The right lung remained normal except for a few coarse rhonchi at the base, a rather inconstant finding.

The wound healed by primary intention and remained clean. The left pleural cavity rapidly filled with fluid, a small amount of which was aspirated for study on the eleventh postoperative day. It was a clear amber fluid which was sterile on culture. His condition continued to be satisfactory with gradual disappearance of his cough and expectoration. He was discharged from the hospital on August 25, 1937, on the thirty-sixth postoperative day, weighing 161 pounds, after walking freely about the hospital for several days.

The excised lung showed a tumor not over 1.5 cm. in diameter obstructing the left upper lobe bronchus. It was somewhat irregular in shape, lying wholly within the lumen of the upper lobe bronchus, approximately 1 cm. up from its opening. There were two indurated areas in the parenchyma of the upper lobe which on section showed a marked bronchiectasis with considerable secretion present. There was an obstructive emphysema of the whole upper lobe. Microscopic examination of the tumor itself showed a well differentiated squamous cell carcinoma. The indurated areas of the lung showed only an organizing pneumonia with no malignant tissue present. The excised lymph nodes showed no evidence of tumor.

The patient's subsequent course has been entirely satisfactory. The left pleural cavity apparently filled with fluid which later coagulated, giving a diffuse opaque shadow over this side. There has been a gradual shift of the heart and mediastinum to the left without excessive displacement or embarrassment. The patient has remained in good health and has had no serious illness since that time. He has only very slight dyspnea which apparently does not handicap him as he has been able to continue his work as manager of a small hotel. It has been unnecessary to even consider collapsing his left chest wall by thoracoplasty as is sometimes necessary if mediastinal displacement causes trouble. He remains in good condition at the present time, five years and three months after the total removal of his left lung for carcinoma. Incidentally, this case is of interest historically as it is the first successful total pneumonectomy for carcinoma in Minnesota or adjacent territory.

For the first time since 1935 and the second time in history, the Hawaiian Board of Health recorded no deaths from diphtheria last year, in spite of the war.

MEDICINE IN MINNESOTA SIXTY YEARS AGO

WILLIAM DAVIS, M.D.
Saint Paul, Minnesota

ACCORDING to the United States census of 1880 the population of Minnesota in that year was 780,000, just two million less than in the last census. Minneapolis, the largest city, had 46,000 and Saint Paul 41,000. Duluth, now the third city in the state, was then a village of 3,500. While physically it was the beautiful state of today, perhaps even more beautiful, because its woods and waters were less disturbed by man, it was a far less comfortable place in which to practice medicine, its country roads for the most part merely beaten tracks across the prairie, with little attention paid to grading, surfacing, and drainage.

Even in the cities there was no block paving and little macadam in the streets, with sidewalks, if built at all, made only of wood. The result was deep dust in summer, mud in spring and fall. Only in winter was the going really good when the streets, little vexed by car tracks, had a uniform coating of ice and packed snow that made wonderful sleighing, so lasting and reliable that the fire apparatus abandoned wheels and went on runners for weeks and sometimes for months.

Railroads were few and accommodations simple. Two lines brought the passengers from Chicago and the trains took fourteen hours for the trip, stopping at eating houses for meals. The Northern Pacific was nearly through to the Pacific coast, the Great Northern, then the Manitoba Road, following soon. There were two roads north to Lake Superior. Trains had just emerged from the old jerky link and pin to the solid coupling. In the cities there were a few street car lines, the cars drawn by one or two horses or mules, the car seats running lengthwise, and in cold weather a few inches of straw on the floor. The driver on an open platform not infrequently got his nose frozen and shivered in a buffalo coat.

Such were the external conditions under which medicine was practiced. The doctor came from a college with at most a three-year course, or he bought his authority to practice from a diploma mill. But the Medical Practice Act was on its way and irregulars were about to be curbed. Even as it was then, it is surprising how little in evidence were the incompetents. The man with three years in a medical school and a year in a hospital represented the best equipment for medical practice.

Few of the counties in the state had their own medical society or one within reach in a neighboring county. The meeting of the State Society gave to many doctors their only opportunity of getting into contact with their fellow practitioners and exchanging professional information and experiences. It was discouraging work to try to keep a county society going, where the members were few in number and widely scattered. Sometimes not even a quorum of one could be raised for a stated meeting. Even in the cities things were not any too good. At least in Ramsey County the meetings were held in some doctor's office, with scanty attendance and little enthusiasm. The office was in a downtown building, heated by a stove and lighted by kerosene lamps or flaring gas jets. Few buildings had radiators and only a few of the most opulent specialists could afford an office with steam heat. Not always could even a single medical paper be furnished. No wonder attendance languished at times, and that at one meeting of the Ramsey County Society the secretary records the presence of three doctors and his, the secretary's dog. In the country, of course, it was impossible to make professional calls without some kind of a team. As the roads were broken out chiefly by farm wagons it was awkward for one horse to travel, particularly in winter, where a single horse could get along only if the shafts were attached to the side of the cutter so that the horse would track with one of a team. In the city most of the doctors' buggies and cutters were drawn by one horse, only a few men being able to drive a pair. In the early years of his practice the city doctor sometimes managed to get about on foot, using the street cars as far as he could; indeed, even so prominent a surgeon as Fenger, of Chicago, through his whole career had no horse. But few doctors failed to set up a rig as soon as they could afford one. While

making a visit the horse would be anchored by a weight, and in cold weather had to be blanketed, a process that must have been attended with some risk of carrying tetanus germs to the patient.

Telephones were not in general use, and although practically every doctor had a telephone in his house, many offices were not so provided. It was largely the custom then for the druggist to own office rooms over his store and to lease them cheaply, sometimes to give them rent free to doctors, the druggist expecting the doctor overhead to steer the prescriptions he wrote to the store below. That this led to abuses at the expense of the patient is easily seen. As a part of this alliance the doctor had his office calls come to the drug store, thus saving the expense of an office telephone. A stranger asking at the drug store to be directed to a good doctor would be very sure to be sent to one who fed his prescriptions to that store. To call a doctor, the druggist's telephone frequently was used by people living in the neighborhood, and the fire department, while not permitting the general use of the telephones in the stations, made an exception in the case of a call for a doctor. A large share of the doctor's calls came directly to the house, where a speaking tube led from the porch to the doctor's bedroom in which there was also an extension from the door bell. Once in the early hours of a still summer morning I was awakened by the sound of a gunshot. I listened for a few moments but heard nothing more and was dropping off to sleep again when my door bell rang and through the speaking tube I was asked to go to the house of a patient a few blocks away. Standing on the sidewalk I found a young policeman who said he had brought the call. On reaching the patient I found he had been seized with a pain so unbearable that he felt he must get relief at once. Alone in the house, with no telephone, necessity drove him to fire a shot from his pistol out of the window to attract attention. This brought the policeman of the beat on the run, and when hailed he consented readily to go and call the doctor. Indeed my patient said that the officer's relief was apparent when he found that the shot was an innocent one. Note that this was described as a *young* policeman. Had it been an older and more sophisticated man he might well have moved away from the sound of the shot instead of toward it, particularly as only a few years before a policeman had been shot and killed when on this beat at night.

The only regular medical journal in the state was the *Northwestern Lancet,* which appeared first in 1881 with only a few small pages of reading matter and advertisements, and no cover. Ten years before there had been a *Northwestern Medical and Surgical Journal* which after a fitful and varied existence gave up the ghost. The *Lancet* lives still in the form of the *Journal-Lancet* which is its direct descendant. For some years after the *Lancet* was started the only other medical publication was the bound volume of transactions of the State Medical Society, and that volume was given up when the *Northwestern Lancet* became big enough to publish the transactions and save the Society the expense of the separate volume.

Sixty years ago the prevalent diseases were quite different from those of today. The mortality reports tell us that the disease causing the largest number of deaths was called cholera infantum, a name that no longer appears in the International List of Causes of Death. Diarrhea and enteritis, grouped together today, now cover the class of cases then listed as cholera infantum, which with its congeners enteritis, gastro-duodenitis, entero-colitis, colitis, and infantile convulsions accounted for twice as many deaths as pneumonia, the next in the list; then came typhoid fever, followed by pulmonary tuberculosis, then called phthisis. Diphtheria, with its related membranous croup, so-called, took a heavy toll. On the other hand heart disease and cancer, now the leaders, then were low in the list. The prevalence of typhoid is accounted for by the fact that much of the drinking water came from surface wells. Minneapolis took its public water supply from the river; Saint Paul's city water came from a lake by gravity only, so that only the lower levels of the city could be reached. Pasteurization of milk was yet to come. Tuberculosis was not recognized as directly communicable. Except for smallpox there was no vaccine, and serums for prevention and cure came much later. For the tuberculous, rest came only when forced by increasing weakness; instead of seeking outdoor life the poor consumptive was likely to be shut up in a closed room under heaped up blankets and comforters lest a draft might aggravate his "cold." Influenza appeared as an epidemic first in 1889, although before that

severe colds were sometimes spoken of as influenza. Infantile paralysis was known as a sporadic disease, but it was nearly 1900 before acute poliomyelitis anterior was recognized as an epidemic. Fitz unmasked the appendix in 1886. For the cases that appeared before that time the favorite name was "inflammation of the bowels," the more scientific names, typhlitis, and perityphlitis not being by any means universally used even by doctors. Operation was done only when a manifest abscess called for incision.

The search for the causes of disease was like groping in the dark and the conclusions arrived at seem fantastic today. A case of typhoid threw suspicion upon a neighboring dungheap. Scarlet fever or diphtheria caused a sniffing for sewer gas. Malaria was attributed to the "miasm" arising from low lands. Colds were caught from drafts, not from a sneezing or coughing neighbor. Although Holmes, and later Semmelweiss, had insisted on the contagiousness of puerperal fever, their teachings were not generally acted upon and little attention was paid to keeping clean the hands of doctor and nurse. Fortunately most confinements were in the home, for the mortality in lying-in wards and hospitals was frightful, even as high as 10 per cent, doctors, nurses and contaminated dressings spreading the infection from case to case. Why, the doctor sixty years ago knew almost nothing about the blood except that there were red cells and white cells that could be counted by the hemometer, which, with the microscope, the stethoscope, and the clinical thermometer were the chief tools in general use. The higher powers of the microscope had been but lately developed and, with increasing skill in the staining of specimens, making visible the minute and transparent bodies called microbes, were revolutionizing the old ideas of pathology, putting an end to the long war between the supporters of the humoral and the cellular theories, and causing both factions to unite against the new science of bacteriology. When it came to treatment, the doctor depended chiefly upon long known drugs, with little reliance upon diet and hygiene. He got little help from the few and ill-equipped hospitals, to which the trained nurse was yet to come.

Only a few bold spirits were opening the abdomen. The skull was operated upon only for depressed fracture, and the joints were left severely alone, for the era of antiseptic and later aseptic surgery was only beginning. Abdominal operations were for the most part ovariotomies, huge tumors that had been repeatedly tapped and whose contents nearly filled the wash tub placed under the table. Hernias got trusses. Pelvic surgery was undeveloped and there was little encouragement for cesarean section, which was not successfully performed, in Saint Paul at least, until 1889. Surgery was limited chiefly to amputations, resections, the removal of growths on the surface, and the handling of fractures and dislocations.

There is a temptation to say something about the many fine men who practiced medicine and surgery in Minnesota in those days. To tell about them all would carry this paper beyond its proper limits and to select a few only would be an invidious distinction. Their memory is enshrined in the homes to which they brought help and comfort, and it could have no fitter memorial.

REMINISCENCES

E. SYDNEY BOLEYN, M.D.
Stillwater, Minnesota

MY FIRST patient was a primitive native American, and it happened in this way. Four of us were, by permission, camping on an Indian Reservation, quite a distance from the agency, which was the nearest place where we could obtain needed provisions for ourselves, two ponies, and one dog. This was in the month of June, 1885, and, as our plans were to stay for a year, we had to make several trips to the agency to bring enough supplies to last us for such a period and do it before winter. As it took three days out, one of rest, and three back, the summer was about gone when we felt our rations were ample. When on one of these trips I called on the Agency Doctor for some remedies and when he found out I was medicine-minded he then asked me to stay in his office while he made a call some distance away. I told him I wouldn't know

what to do in case any sick ones called. He said, "Oh, just look around for something—anything you find that won't do them any harm—give it, and with a lot of instructions, for if it does not work you can always blame it on their own carelessness." So I became the Agency Doctor, *pro tem.* An invitation to supper at the doctor's house was looked forward to, as the doctor's wife (bless her) was not only a very charming woman, but also a most excellent cook, and I was comfortably ensconsed in the doctor's swivel chair, feet on the desk, and my thoughts pleasant in anticipation of that supper, when a whoop rudely disturbed my dreams. I looked around and saw a squaw who, while not remarkable in height, was certainly very extraordinary in circumference. I looked at the door, then at her, and wondered how she got in—but there she was. She whooped again, pointed to her stomach, then to her mouth, by which gestures I supposed she wanted medical attention.

Following the doctor's instructions, I took stock of the pills and potions in his surgery and decided on some powders in a tin box, one kind in a blue paper, the other in white. Among the few office fixtures was a wooden bucket, half filled with water, on which sailed a rudderless tin cup; this helped me to solve the problem of medication. I gave her the powder in the blue paper with some water to wash it down; I then put the white powder in the cup, added some water, stirred up the mixture and by motions indicated she should swallow this without delay—which she did. She had hardly downed this when she commenced to roll her eyes and whoop to beat the band. I had to turn about to hide my desire to laugh—she looked so funny. When I looked around she was gone. Then my conscience—it is very inconvenient to have one—commenced to work and smote me viciously, and I knew remorse, until another whoop demanded my attention. There was the same squaw with five more, all pointing toward their tummies and open mouths. I accommodated them as long as the powders lasted; "a good time was had by all." I wondered how they would feel the next day or that night, and also if I had not started something for the doctor. When they were gone I locked up the office—I thought this best—and silently stole away to the doctor's house and told his wife what I had done. It is fortunate that it is next to impossible to perish from laughter, but I think the doctor's good wife then came very near it; not so the doctor, who, when told, said: "Hell, those Seidlitz powders were for the white folks around here and not for the Indians."

My next adventure connected—if remotely—with medicine happened while I was House Physician at St. Barnabas Hospital and a student at the Medical Department of the University of Minnesota in the year 1890. At that time many interns, or house physicians or surgeons, as they were then called, were undergraduates and called doctors, as were medical students just as soon as they entered a medical school, for no good reason that I know of. Dr. Perry H. Millard had now succeeded in establishing a real medical school, up to the standards of the best ones in the states, and, when this became known, the number of students increased so rapidly that a shortage in necessary materials for teaching, especially in anatomy, became acute. I heard Dr. Hendriks complain about the shortage of dissecting material, so, when on one Saturday at a football game I mentioned this to Harry Lee d'Arms of Stillwater, an Ann Arbor student intern at the Minneapolis City Hospital, he told me that a man, a county charge, had died at the Stillwater City Hospital and had not been claimed by any of his relations. Although this man had some money he was, by the influence of a relative in the "Marble Business," put on the county. This relation—so the story ran—would then get his money for putting up a stone, or marker, at his grave. Harry and I decided to act at once but since it was on a Saturday when Dr. Hendriks could not be reached for a requisition (he was the only one in the state then who could issue one), we decided to take a chance without it. We went to Stillwater, claimed the body, and early Monday morning I, with the body, left by train for Minneapolis. Arriving at White Bear I got a telegram ordering me to "bring P. back." I got P. transferred to the Minneapolis branch. At the Minneapolis Union Depot another "bring P. back" awaited me. I hurried out and got a dray man, had him drive as fast as he could to the University Medical School. There the dray man gave the box a pull so that it barely balanced on the rear end of the wagon when he suddenly stopped and excitedly asked, "Is that a stiff?" to which I answered, "Yes." At that he jumped up on his dray, grabbed the lines and cut the horse a smart clip with his whip. The horse jumped,

the box slid off and landed on the sidewalk, and the man went his way without his pay. I got the janitor, Mr. Rose, had him take care of the box and what was in it, and went for Dr. Hendriks for the now badly needed requisition. Dr. Hendriks was lecturing when I rapped on the door, which he opened, and when he saw me he said—without giving me a chance to explain or give a reason for my temerity—"any man old enough to have hair on his face ought to know better than to disturb me while lecturing," slammed the door shut in my face, and that was that. I hurried up to see Dr. P. H. Millard, the Dean, and was lucky in meeting him as he was leaving his office for Saint Paul. Just then another "bring P. back" message was handed me by Rose. With that, my explanation and Rose certifying to the stiff, Dr. Millard (he had lots of hair on his face, too) disturbed Dr. Hendriks, got the requisition and also a handsome apology. Armed with the requisition I went to the depot, met the undertaker and a detective, who pompously put his hand on my shoulder and said, "I arrest you in the name of the law of the Commonwealth of Minnesota." When I asked the reason, he said, "for taking a stiff without a requisition." Then came my hour of triumph when I pulled out the precious document and explained that in the hurry out of Stillwater I forgot to hand it to Mr. C., the undertaker, and this was the last of it as far as I was concerned. However, the next morning the *Minneapolis Journal* had a large picture of Dr. Hendriks right in the center of the front page and in large letters the label, "Body Snatcher." Mr. P., having died from typhoid, then a very fashionable disease, was very lean and made fine dissecting material, and Dr. Hendriks had many demonstrations out of him.

This was the year 1890, also the year when Dr. Koch announced his discovery of tuberculin, which, with its promises, electrified the world. The Medical School and Dispensary was then located across the street from St. Barnabas Hospital. A year later, from near and far, came those afflicted with tuberculosis to get the promised cure by this new treatment, but the University was not prepared to give it. On the spur of the moment I wrote to Dr. Koch, asking for tuberculin, stating I knew the technique, and signed this as House Physician, St. Barnabas Hospital, which in Europe meant a lot but here nothing at all. I posted this letter and promptly forgot all about it until, one day, I received a notice from the Custom House to come and get a package and to pay charges on same.

It proved to be a supply of tuberculin direct from Berlin. Now that I had it, I did not know what to do with it. Among the doctors who had patients at St. Barnabas was Dr. J. Clark Stuart, Professor of Pathology at the University, who, I noticed in going the rounds with him, took a very keen interest in his patients. I went to him and he said, "This is a package from Heaven. We will see Dr. Nothnagle." The latter was an enthusiastic and thorough worker in general medicine at the dispensary. He rounded up quite a number of cases of pulmonary tuberculosis, selected those he thought resistant to other forms of treatment, graded them so that of two of each kind one would receive tuberculin and the other just scientific neglect and serve as a control. Some were hospitalized, but most of them, not very far advanced, stayed at private homes or boarding houses. All of them received special instructions as to rest, exercise, diet and personal hygiene. In six months none of those receiving tuberculin was alive. At first they gained in weight but soon became increasingly anemic and flitted to happier hunting grounds. All of the controls were alive after six months. Most of them improved in health and some were apparently cured or the disease arrested. This was undoubtedly due to a more understanding, sympathetic, personal attention, and to rest and diet.

I think our experience with tuberculin was quite general and fulfillment of the high hopes of cure or prevention of this dreadful disease vanished after many disappointing trials. Since then its real value as a diagnostic agent has been demonstrated and it has proven a boon and an invaluable gift to humanity.

In 1894, the medical care of the inmates of the State Prison at Stillwater was administered by a visiting local doctor who came once daily. A guard, who had been a hospital steward during the Civil War, looked after them in the meantime and also did the nursing, if any.

The twine and shoe factory machinery, worked by the prisoners, caused some accidents and, as the visiting doctor was not always available for such emergencies, the prison management decided to employ a full-time graduate as intern and to bring the so-called hospital up to more modern standards. Dr. Perry H. Millard recommended

me for this position because of my hospital experience and so, after graduating in June of that year, I became the first full-time medical man at this institution. I had to examine all the prisoners there, those who came and those who left. A small laboratory was added to the hospital and surgical instruments were purchased.

At that time the inmates numbered between 550 and 700. Twice a day the Deputy Warden made the rounds and picked up those who wanted to see the doctor, and usually from seventy-five to 100 or more felt this need. That was too many for proper attention and the problem was how to eliminate the "non-sick" or loafers. Cole Younger, who was my runner, made a suggestion that worked; he said that there were a couple of barrels of cod liver oil in the storeroom that had been there for a long time; "how would it be to give the *just loafers* some for a treat?" So, the "float" was born. A float was, at that time, the name of a popular drink; the composition was charged water in a tall glass upon which brandy was poured gently so that the brandy would stay on top and the drinker would enjoy the mingling of the two fluids. However, the float given the "loafers" was not that kind but consisted of rich brown, cod liver oil upon which floated red pepper and quinine. This reduced the sick call to those who really were ailing, and seldom more than thirty came any day.

In Stillwater, as elsewhere, typhoid was very prevalent, and early recognition was desirable when possible. Helpful in this was the diazo-reaction just coming into use. The visiting doctor brought some specimens of urine for examination and in several, this reaction indicated typhoid, and when this proved correct, some of the other doctors sent some specimens, too. I became interested in these cases and inquired about the water and milk supply, traced these and found out that many of the cases appeared along the route of certain milk wagons and that the cows donating the milk for these wagons were watered at Lake McKusick—and thereby hangs a tale. One day, while down town, one of the "City Fathers" stopped me and, in no uncertain terms, told me to lay off on that typhoid stuff.

A few of the inmates were surgical subjects and the hospital was now fairly well equipped for a few of these cases. One was a tuberculous ankle, so badly diseased that amputation was necessary and was done. During the legislative session in 1895 a legislator made the charge that arms and legs were cut off prisoners for rheumatism. An investigation was ordered and held at the State House. The hearing was conducted by Judge Flandrau; when the diseased ankle and foot were shown and the evidence gone over, the Judge promptly discharged the case, after making a few very caustic remarks (and he could be caustic) about the complaining legislator. However, this individual got his last say-so and revenge by having some regulations established whereby any prisoner requiring a surgical operation must have a guardian appointed who must give his full consent before an operation could be done. How long this ruling was in effect, or whether it still is, I do not know.

After leaving the prison, I joined the regular profession as a practitioner in Stillwater. This was in the so-called "Horse and Buggy Days," an expression intended to emphasize the hardships doctors who indulged in country practice had to put up with, although I did not find it so very hard when one could get around with a horse and buggy; but with a horse and sleigh in January, February, March, and into April, the going was really tough and sometimes dangerous. Many of the old fellows, still in practice, could, if they would, tell of experiences that required courage and devotion to duty.

At that time about twenty-one men practiced "the healing art" in Washington County. Most of them were regulars, with three homeopaths and one eclectic. Some of them were not graduates in medicine but had exemption certificates. Several midwives were also on hand, and they were quite busy, too, giving "first aid." Doctors' offices were not then, as now, well equipped. A few chairs, a desk and swivel chair, an examining table, and sometimes a bookcase, made up the furniture. Other professional requirements consisted mostly of a few surgical instruments, in which was included an amputation set, bandages, dressings, fracture splints or material for making them, some tablets, carbolic acid, and sometimes H_2O_2, also an alcohol lamp, nitric acid, Haines solution, and two or three test tubes. For calls he had a medicine case, usually well supplied, a pocket instrument case containing a few needles, sutures, a pair of scissors, a "Bistoury" and in his upper vest pocket a thermometer. His obstetrical case was usually the best looked after and most frequently used. His

medical library was conspicuous rather for its near-absence: a Gray's Anatomy, a volume or two on surgery, practice of medicine, diseases of children, gynecology, obstetrics, and rarely a medical dictionary. The treatment of wounds consisted of washing with soap and water or irrigating with a carbolic acid solution, not always well shaken up (in pus cases, peroxide), and was usually topped off with a generous sprinkling of iodoform. The surgeon's hands or instruments were given no special attention. The antiseptic principles or rules (this was the antiseptic age) were not well understood. As an example: an old doctor practicing in the southern part of the county, took a patient to a Saint Paul surgeon for an abdominal operation. At the operation some interesting conditions were disclosed which the operator wanted the old doctor to palpate, so he said, "Scrub up and sterilize your hands and feel of this," to which the old man answered, "Oh, I did that before I left, early this morning."

Vaccination and quarantine for some of the communicable diseases were the only preventive measures known or practiced. Typhoid, tuberculosis, diphtheria, pneumonias, influenza, scarlet fever, and measles were the most common ailments and were treated symptomatically with nursing of the most primitive kind. The death rate was quite high, especially in diphtheria. This terrible scourge was given, beside internal medication and diet, heroic local attention by painting affected parts, if reachable, with strong solutions, gargles, sprayings, inhalations and forceful detachment and removal of the false membranes as they formed, and intubation, all too often of no use. The helplessness in these cases was only relieved when antitoxin came into use and its prompt and miraculous effect demonstrated.

I think this was largely responsible for a less suspicious attitude toward newer therapeutics and the many new scientific discoveries now becoming available for practical use. These bewildered the old fellows, as they found it hard to understand them and, besides, were chary in displacing the Old for the New, or, rather, unable to adjust themselves to the New. The younger men, more alert, better educated, easily and eagerly fell in line with anything that proved beneficial and practical.

It is well to remember that, up to quite recent times, the practice of medicine was comparatively unscientific. There were not, as now, well equipped hospitals or richly endowed institutions for highly technical research at the beck and call when help in difficult or obscure cases was needed, nor, perhaps, the willingness of the people to submit to such had there been, as a suspicion toward anything out of the ordinary—unless it were a gold brick—was then harder to overcome.

If now, in 1942, when Minnesota Medicine celebrates its twenty-fifth anniversary and reviews the wonderful advancements in medicine toward a science, we feel inclined to be amused at what has gone before or those who practiced it, keep this in mind, that the therapeutics of today may be out of date and amusing tomorrow. Therefore, let us think of these old fellows, now no more, as honest, kindly, efficient for their time, and doing pretty good work with what they had; let us bare our heads and reverently intone *"Requiescat in pace."*

ARMY DOCTORS IMPORTANT

Military doctors play a decisive role in war between nations and in mankind's peacetime fight against disease. Their triumphs in both kinds of war were reported by Col. Edgar Erskine Hume, of the Army's Medical Field Service School at Carlisle Barracks, in a public lecture at the New York Academy of Medicine.

"Half a million men can turn the tide of a war, even in these days of huge armies," Col. Erskine declared.

The United States, he pointed out, might have had that number of men put out of action in World War I, not by enemy guns but by a single disease if our Army had not been effectively protected against typhoid fever. In the first World War there were only 1,500 cases of typhoid fever instead of half a million as would have been expected on the basis of the numbers affected by this disease in our war with Spain in 1898, before doctors knew how to vaccinate against typhoid fever.

"In all past wars disease has struck down more soldiers than all the combined effects of the enemy's weapons," Col. Hume declared. "The soldier's duty is to fight, not to die, for his country. The Army's medical department has the task of keeping him fit, 'To Conserve Fighting Strength,' to quote the motto of the Medical Field Service School, Carlisle Barracks, Pa."

Recalling that the disastrous ending of Napoleon's Russian campaign was the result of an outbreak of typhus fever, to which the Russians were immune but the French and their allies were not, "Who knows but what something of this kind may not happen in the present war in Russia?" Col. Hume asked.

"Horrible though war is, it has stimulated medical advances," he continued. "Some of the world's great medical discoveries have been made by military surgeons, particularly in connection with field service. Every war has added to the sum of medical knowledge."

—*Science News Letter,* December 19, 1942.

GROUP HOSPITALIZATION

ARTHUR M. CALVIN, Executive Director
Minnesota Hospital Service Association
Saint Paul, Minnesota

"Group Hospitalization," practically an unknown term nine years ago when the Minnesota Hospital Service Association was organized, is now a nationally understood phrase, as familiar to the every-day citizen as it is to the medical profession and to hospital personnel.

In less than a decade, group budgeting of hospital care has become nationally significant. Today, 11,000,000 persons throughout the United States are budgeting their hospital bills through seventy-six non-profit Blue Cross Plans for hospital care. These plans operate on a voluntary basis and are approved by the American Hospital Association.

Employed persons of limited means, reluctant to receive free or part-pay hospitalization, who formerly made valiant efforts to pay their hospital bills from limited resources, have welcomed enthusiastically the development of these non-profit plans which enable them to budget their hospital service conveniently in regular payments.

The Minnesota Hospital Service Association is a pioneer in the group hospitalization field, being the second oldest and the fourth largest of the Blue Cross Plans.

In 1933, when seven Saint Paul hospitals organized this plan, the medical profession of Minnesota, with characteristic foresight, took an active interest in its development. Various aspects of the plan were freely discussed by the hospitals and the medical profession and these discussions were printed in the early issues of Minnesota Medicine.

Because of the attitude of kindly interest of such men as Dr. Carl B. Drake, editor of Minnesota Medicine, who, with many others in the medical profession, believed that a group hospitalization plan could be carried out without interfering with the relationships of patient and doctor, the Minnesota Hospital Service Association has been able to develop rapidly.

Operating on a voluntary basis, the plan has proved to be of tremendous value; first, to the patient; second, to the hospitals; third, to the medical profession, and fourth, to the community.

Today, after nine years of public service the Association's Blue Cross Plan is no longer an experiment. It has definitely proved that non-profit group hospitalization plans can be financially sound and that actuarial experience on the number of subscribers who may be hospitalized and the amount of care they may use, can be computed.

The Minnesota Hospital Service Association, which started with seven hospitals, now has 109 affiliated hospitals throughout the state, which are most cordial in their relationships. The hospitals do not receive profit from the plan, but are assured of prompt payment for hospital service rendered to Blue Cross Plan patients, just as the subscriber is assured of prompt and adequate hospital care when he is ill.

At the present time, 507,000 persons in Minnesota (one person in every five) subscribe to the Blue Cross Plan. The enrollment is distributed as follows: 366,000 in the Twin Cities; 50,000 in Duluth; 91,000 in the rest of the state. Through the coöperation of the Minnesota Farm Bureau, 25,000 farmers and their dependents have been enrolled. It is estimated that by the end of January, 1943, 515,000 persons in the state will be budgeting their hospital care through the Blue Cross Plan of Minnesota.

The outstanding enrollment record of the Plan is surpassed only by its record of service to subscribers. One thousand subscribers are in affiliated hospitals daily. Since 1933, 220,000 subscribers have received hospital care amounting to $6,653,000.00. In the last nine years 26,000 babies have been born to Plan subscribers who have benefited under the maternity clause in the Association's contract.

During 1942, alone, the Plan will pay nearly $1,750,000.00 to its affiliated hospitals for the care of its subscribers.

Through the Blue Cross Plan, hospitals can render greater service than ever to their communities, for when the financial hazard is removed, more people can avail themselves of hospital care when they need it.

Today, with our nation at war, it is imperative that people be able to avail themselves

promptly of hospital care, and so take care of their health, for millions of work days each year are lost through illness. The Government has recently commended the Blue Cross Plan, for it recognizes the contribution the Plan is making to the war effort by helping reduce the number of work days lost through illness. According to national statistics, Blue Cross Plan patients stay in the hospital two days less than other patients. This is because, with the financial hazard removed they seek hospital care earlier and consequently return to normal life and to work more rapidly. It is estimated that in 1942 alone, over 2,000,000 work days will be saved the nation in this manner.

Minnesota's Plan today enjoys financial soundness, but prolonged or unnecessary care to subscribers can quickly and greatly jeopardize this soundness. It is in this respect that such a plan is dependent upon the medical profession who can control, to some extent, a subscriber's need for hospital care as well as the length of time over which he will need such care.

The Minnesota Hospital Service Association's accomplishments in the group hospitalization field were recently acclaimed by officials in medical, hospital, and government circles. At a dinner in October, 1942, celebrating the enrollment of the one-half millionth subscriber to the Association's Blue Cross Plan, Governor Harold E. Stassen remarked:

"This program of the Minnesota Hospital Service Association is a splendid example of a democratic method to solve a problem of community interest. The state has an obligation to coöperate with an organization of this type and has so demonstrated in the past. The totalitarian way of life is for the state to do everything and the people to follow its dictates. Our democratic way of life is for the people to solve their problems in a voluntary way with the utmost cooperation of the government and not for the government to do it all.

"If the government was to carry out a plan of this type it would cost considerably more to administer the plan and it would take a greater number of employes. I wish to congratulate this organization on the service it is rendering to the people of Minnesota."

On this same occasion, the Plan received congratulations from such national figures as Thomas Parran, Surgeon General of the United States; Cordell Hull, Secretary of State, and James Forrestal, Acting Secretary of the Navy. Surgeon General Parran's letter read:

"The Minnesota Hospital Service Association has made a splendid contribution to the conservation of the nation's health in wartime through enlisting a half million members under the Blue Cross Plan.

"Prompt hospital care in sickness and injury will do much to reduce the time lost because of disability in our war industries.

"Please accept my congratulations on your achievement."

A telegram from Cordell Hull stated:

"I am glad to extend my felicitations on this fine record of public service and to send best wishes for the continued success of your Association in the future."

James Forrestal, Acting Secretary of the Navy, commented:

"It is a cause of genuine gratification to our United War effort and to me personally to learn that Minnesota has successfully completed the enrollment of half a million of the good citizens of your state in your Blue Cross Plan.

"The maintenance of sound bodily health is a tap root of national ability to survive in this vast planetary try-out of the quality of whole peoples. But, more than that, your Association brings an opportunity to many thousands of citizens to work together in an unselfish cause, whatever be their other tasks or affiliations, and this in itself is a vital factor no less important than the more obvious physical objectives you have in view.

"Please accept for the Minnesota Hospital Association my very true congratulations and my best wishes for the continuance of a good start towards a communal unity demonstrated by daily work."

The great strides that the Minnesota Hospital Service Association has been able to make in the group hospitalization field could never have been made if the Plan had not received splendid coöperation from physicians, hospitals, nurses, group leaders, employers, labor and civic leaders, clergymen, public officials, the radio and the press.

With the continued coöperation of these forces, the Blue Cross Plan will not only continue to develop and to render valuable service to the people of Minnesota, but it will also continue to be a leader in the group hospitalization field.

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL

A. J. Hertzog, M.D., and S. V. Lofsness, M.D.
Pathologists

Presentation of a Case

Dr. Mitchell: This case is that of a forty-two-year-old colored woman who was admitted to the Minneapolis General Hospital on October 23, 1942, in an unconscious state. The history was obtained from her husband. She had been employed in a laundry as a steam presser, and her past health had been good. On October 21, two days prior to her admission, she was suddenly seized with severe epigastric pain that was followed by nausea, diarrhea and a feeling of faintness. She was seen by a private physician who told her she had gall-bladder disease and gave her some medicine. However, her condition became worse, she vomited frequently, her eyes became yellow, the epigastric pain persisted, and she became confused. Shortly before admission she became unconscious.

Physical examination on admission revealed a well-nourished, well-developed negress in coma. Her temperature was 99.4 degrees by rectum, her pulse rate 110 per minute, and her breathing was labored. The scleræ were yellow and the skin showed evidence of jaundice. Examination of her heart and lungs was negative except for a soft systolic murmur over the aortic area. The liver was enlarged and extended 4 cm. below the right costal margin. There was some rigidity of the abdominal muscles in the epigastrium. The remaining examination was negative.

Laboratory examination revealed her hemoglobin to be 86 per cent. Her leukocyte count was 5,000 with 92 per cent neutrophiles. Rytz and Kahn tests were negative. Urinalysis showed dark brown urine with two plus albumin, nine to ten red blood cells and two to four leukocytes per high power field. Her icterus index was 60 units, and van den Bergh test gave a prompt direct reaction. A serum amylase test showed 281 Comfort units. Her blood sugar was only 35 mg. per cent, and the carbon dioxide combining power was 42 volumes per cent. The prothrombin level was 76 per cent, and total cholesterol was 236 mg. per cent.

The patient was given glucose intravenously and treated symptomatically. Following the glucose, the blood sugar rose to 220 mg. per cent and she quickly recovered consciousness. She vomited almost continuously during the first twenty-four hours of her admission. Her vomitus during this time was approximately 2,000 c.c. After that, duodenal suction was instituted and a moderate amount of fluid was aspirated which was positive for occult blood, but was negative for bile pigments. The vomitus had a fetid odor. On October 26, her blood urea nitrogen was 52.5 mg. per cent. A stool specimen was obtained with difficulty, and was clay colored. It contained only a trace of urobilinogen. The icterus index rose to 83 units. A twenty-four-hour urine specimen showed bile, but a quantitative urobilinogen determination showed only a trace. She again became comatose. A blood urea nitrogen on October 29 was 155.4 mg. per cent. Her temperature rose to 104.8 degrees and she expired on October 31, the eighth day of her admission and ten days after the onset of her illness.

Dr. Hertzog: This case presents a diagnostic problem and has many interesting features from the laboratory standpoint. We have a forty-two-year-old negress who apparently was well until ten days prior to her death. She was admitted in coma with a history of severe epigastric pain. I imagine acute pancreatitis was considered as a serum amylase test was done. However, the results were within the upper limits of normal. An elevated serum amylase level is very helpful in the diagnosis of acute hemorrhagic pancreatitis. She was jaundiced. Slight jaundice is hard to recognize in a negro. However, her icterus index was 60 and later rose to 83 which represents rather severe jaundice. The findings in the urine and stool were that of an obstructive jaundice. A van den Bergh gave a prompt direct reaction as found in obstructive jaundice. However, we have to keep in mind that in obstructive or regurgitation jaundice, the obstruction may be intrahepatic as well as extrahepatic and often the laboratory is of little help in separating these two types of obstruction. Liver biopsies done with a small trocar, with little discomfort to the patient, may prove useful in these cases. The elevated urea nitrogen was probably extrarenal in nature associated with vomiting and dehydration. Mann showed that after the removal of the liver in dogs, the formation of urea ceases with a resulting drop in the level of urea in the blood. Hence, in severe uncomplicated liver damage, one would expect a drop in blood urea rather than an increase. The amino acids, however, may be increased as the normal deaminization which occurs in the liver is stopped. There is a case reported in the literature where uremia as the result of tubular kidney damage, followed traumatic lacerations of the liver. The relationship between the liver and kidney pathology in this reported case is not clear. Theoretically it would be possible for the kidneys to be damaged by the same toxin that destroys the liver.

Dr. Peppard: I would think of liver disease, although I do not think the story is quite the usual one for acute atrophy of the liver. There certainly is not anything to suggest the diagnosis of pancreatic disease.

Dr. Moosnick: We were unable to get a history of the patient having taken any toxic drugs. The mucous membranes showed no evidence of any burns.

Dr. Hertzog: Dr. Mitchell will now give the autopsy findings.

Dr. Mitchell: The body was that of a well-developed, well-nourished negress. Although the skin

was dark, definite jaundice could be recognized. The peritoneal cavity appeared normal. The liver was flush with the costal edges. The liver weighed 1,600 grams. The capsule was smooth and it had a bright yellow color. On section, the liver was smooth and soft, with a bright yellow color. The centers of the lobules were red. The gall bladder appeared normal and the bile ducts were patent with no evidence of any obstruction. The gastro-intestinal tract appeared normal except for severe superficial erosion of the mucosa in the terminal portion of the esophagus. This did not extend into the stomach. The kidneys weighed 200 grams and 280 grams each. Their surfaces appeared swollen and bile-stained. The mucosa of the urinary bladder was hemorrhagic. The spleen was of normal size. The heart and lungs showed nothing of note other than confluent bronchopneumonia in the lower lobes of the lungs.

Dr. Lofsness: I will show the microscopic slides in this case. Grossly, the liver resembled severe fatty metamorphosis but microscopically one sees severe necrosis of the liver parenchyma. The central portions of all of the lobules are necrotic. Only a few viable liver cord cells are seen at the periphery of the lobules. There is also some bile pigment in these parts of the lobules. A great deal of liver tissue has been destroyed. There is no evidence of repair, bile duct proliferation, or fibrosis. The spleen shows only congestion. This section of the lung shows pneumonia, with fibrin and leukocytes filling most of the alveoli. The glomeruli and blood vessels of the kidneys appear normal. However, it has to be remembered that the glomerular capillaries can leak proteins and give albuminuria from a trivial injury with no histologic changes. Some of the collecting tubules are filled with pink granular material as seen after transfusion reactions. There is no history of any transfusion to account for this. If the substance is hematin, it could be due to hemolysis. The tubular epithelium appears intact.

Dr. Hertzog: The histologic picture in the liver that Dr. Lofsness pointed out to you is typical of acute degeneration of the liver. The term "acute yellow atrophy" is often applied to this type of liver disease. The name is really a misnomer, as frequently the liver is larger than normal and red in color, rather than yellow. Hence the term, acute degeneration, is preferable. The urine in these cases at times may contain leucine and tyrosine crystals. Some of the chronic cases may develop eventually a type of cirrhosis that is difficult to distinguish from the ordinary type of portal cirrhosis. The mild cases that recover are usually called acute catarrhal jaundice. The findings in the kidneys are not sufficient to account for the elevated blood urea nitrogen. The uremia appears largely due to extrarenal factors. The patient vomited a great deal and lost considerable fluid during the first part of her hospital stay. An esophagitis is frequently seen at postmortem in a patient who has regurgitated the acid stomach contents prior to death.

Dr. Moosnick: Does this liver look like those found in severe alcoholism?

Dr. Hertzog: No, in chronic alcoholism the usual finding is a fatty liver.

Dr. Lofsness: Acute degeneration of the liver is an uncommon disease of unknown etiology. Some cases occur during pregnancy, and some are due to drugs such as sulfanilamide, neo-arsphenamine, chloroform and cinchophen. Occasionally it follows extensive burning of the skin or thyrotoxicosis. Many cases, however, such as this one, are not well understood. They tend to occur in younger people, often have an abrupt onset, with no known precipitating factor. The principal lesion is autolysis of the liver. This suggests death or injury of the hepatic cells without inactivation of the intracellular enzymes. Chemicals such as chloroform, toluene and salicylic acid will do this. Substances such as strong acids, phenol and formaldehyde kill cells but also inactivate ferments and consequently fix tissues, preventing autolysis.

On a few occasions, biopsies of the liver have been taken from people with acute hepatitis. The main change is swelling of the liver cells. This narrows the sinusoids, reducing the blood flow, and consequently the oxygen supply. Anoxemia favors acidosis, as seen in an overworked muscle, or excised tissue. Slight acidity will kill cells, as seen in tissue culture. Also, the intracellular pepsin-like enzyme acts best in an acid environment. Inasmuch as the centers of the lobules have the poorest blood supply, they usually are most severely attacked. Recent studies suggest that blood flow in the liver is influenced by valve-like musculature around the sinusoids under nervous control, and this may be concerned.

In any event, the lysed cells liberate protein cleavage products into the circulation, such as albumoses and amines, which are highly toxic. Amino acids are formed, appear in the blood in excess, and are excreted in the urine. Also, the damaged liver is unable to stabilize the blood sugar, so that hypoglycemia occurs frequently. You will recall that our patient entered with hypoglycemic coma. It seems that the malignant course of this disease is due more to the toxins formed by autolysis, and the loss of hepatic function, than to the precipitating toxin.

Anatomic Diagnoses: (1) Acute degeneration of the liver; (2) bronchopneumonia; (3) acute esophagitis; (4) jaundice.

LOWEST DEATH RATE FROM PNEUMONIA REPORTED

The lowest pneumonia and influenza death rate on record among its industrial life insurance policyholders was achieved in the last annual cycle, September, 1941, to August, 1942, the Metropolitan Life Insurance Company announces.

During that period the average pneumonia-influenza death rate was equivalent to 32 deaths per 100,000 persons. This is 21 per cent less than the previous low record made the year before and 63 per cent less than the rate five years before.

Most striking is the change in the picture during the winter months when pneumonia and influenza deaths reach their maximum. During the winter of 1936-1937, considered an average winter at that time, pneumonia and influenza deaths reached an extremely sharp peak in February with a rate of more than 175 deaths per 100,000 persons on an annual basis. At the end of February, 1942, the peak was just over 50 deaths per 100,000 persons on the annual basis. The death rate for the winter months was 70 per cent less than in the winter of 1936-1937, and the seasonal mortality curve has flattened out so as to be "almost beyond recognition."

The life insurance company warns, however, that the continued prevention and control of pneumonia is the concern of every man and woman and that no common cold can be considered lightly. Signs or symptoms of more serious trouble call for prompt medical attention.—*Science News Letter,* December 19, 1942.

THE ASIATIC CHOLERA IN SAINT PAUL

JOHN M. ARMSTRONG, M.D.
Saint Paul, Minnesota

(Continued from December Issue)

The Board of Health made its first report to the Council on June 11. The fact that such a report was made is all that is preserved in print of the activities of that body and this statement in the minutes of the Common Council is the only official record of the cholera in Saint Paul until the succeeding epidemic, which will be taken up later. It must be remembered that it was feared that the fact that cholera existed here might get abroad and deter immigration. Knowledge of the matter was kept as quiet as possible. Immigrants meant business and money, and both were sorely needed here. The Council, then, when receiving reports from the Board, tabled them; thus the report did not appear on the minutes and even the newspapers did not print them and almost ignored their presentation. This attitude of the city government and newspapers in regard to epidemics is still often followed. The report, as I have stated, will not be found in the printed record. Fortunately, through the courtesy of the custodian of the Courthouse some years ago, I came upon the written minutes. Subsequent reports could not be found. The report is as follows:

"The Board found a young man sick on Third Street with the disease which has been prevailing to a moderate extent among immigrants upon the decks of our steamboats, to whom due aid and comfort was administered, and as soon as he was sufficiently recovered to be removed, he was provided with comfortable quarters. He is now very nearly well. A man named ————, an Irishman, in a dying condition when the Board organized, was visited and after death his remains had decent sepulture, through the instrumentality of the Board and Mayor Olmsted. A German of the name of Frederick Altman, was found in a dying condition yesterday morning in the suburbs of the city and was removed to the home of a benevolent citizen nearby where he had the best attention of the inmates of the domicile and the Board while he lived. He died last night and was buried today."

The Board also stated that they had been unable as yet to procure a building for a hospital. Bishop Cretin then made the Board a proposition as follows: "That the city could have the use at reasonable expense, of ample apartments in the hospital now in process of erection under his superintendence as soon as it was finished, which he thought would be by the first of July." St. Joseph's Hospital could not be used, however, and it was imperative that a building be secured at once. The old log chapel of Saint Paul, erected in 1841, at this time being used as a school by the Sisters of St. Joseph, was secured, and shortly after this event, opened as a cholera hospital.

When the steamer *Galena* drew up to the landing in Saint Paul early in the morning of June 16 she had nine ill with cholera aboard, one patient, a cabin passenger, in extremis. He was carried to Doctor Goodrich's office where he expired at 9 a.m. He was a physician named A. Sargent of Meadville, Penn-

sylvania.[2] Most of those who died or who had the disease in Saint Paul were strangers so that their names are not remembered and were in many instances unknown. Saint Paul citizens did not entirely escape. Among the latter was Col. Daniel H. Dustin, United States District Attorney. He was orator of the day on July 4, was taken ill a few days later and died on the tenth at the Winslow House (where the Forepaugh Block now is at Seven Corners). An infant daughter of his died a few days later at the home of Samuel Abbey.[3] On June 19 the fifth death occurred in one family in Upper Town, name unknown, and another member of the family was stricken. On July 25 there were two more deaths, one a Miss Bridgit and the other Dr. Charles Ludwig Vicchers,[4] who contracted the disease from a man he was attending. He lived but five hours after the onset of symptoms. The daughter of The Reverend Van Ingen, rector of Christ's Church, was taken ill with cholera when the steamboat she was on was ascending the river opposite Kaposia. She died a few days later.[5] On July 22 Charles D. Fillmore, a half-brother of ex-president Fillmore, died of dysentery, the papers stated, as no doubt his obituary would be widely circulated. He was stricken with cholera while driving from Saint Paul to Stillwater but managed to get back to town before he died.[6] Three days later a child named Hoffman and a niece of Fillmore's wife died of the same disease. After Fillmore's death, whenever a livery team started out to be gone for several hours it was customary for the livery man to put a bottle of cholera medicine under the seat of the vehicle. The popular cholera medicine among the people was Perry Davis' Pain Killer, a mixture of whiskey, tincture of opium and tincture of capsicum. It was taken internally and also applied to the abdomen. On August 2, two persons, Edward K. May, a prominent merchant, and an unknown woman died. On July 25 the steamer *Galena* again brought cholera patients into the city and several deaths had occurred on the boat on its way up the river. My mother, who came to Saint Paul the last day of July, tells me that a man died of the cholera at the Winslow House shortly after her arrival. He and his wife had just arrived from the South on their wedding trip. Doctor Potts was the man's physician. My mother's aunt, later Mrs. Willis A. Gorman, volunteered to care for the man while my mother endeavored to render consolation to the young wife.[7] A servant in the home of Judge Sherburne was found ill in bed one morning with cholera. Dr. A. G. Brisbine was called. He secured a Sister of St. Joseph to care for her but she died the same evening.[8] There were nine in the Sherburne family and two other servants, but none of them contracted the disease.

Much more, no doubt, could be added to this account, had this investigation been undertaken forty years ago instead of recently. Possibly my mother is the only person now living who has personal recollection of the cholera in Saint Paul in 1854. It would seem that there was considerable more cholera in Saint Paul than most people would now believe, as I certainly have been able to

---

[2]Doctor Sargent was accompanied by his daughter. In October, a Mr. Kennedy came to Saint Paul to take Sargent's body back to Meadville for burial.

[3]Both Dustin and his daughter were attended by a homeopathic physician named Geo. A. Sperry. Sperry left Saint Paul some years later. Samuel Abbey's house was on Fourth Street about where the entrance to the J. J. Hill Library now is. Later the house was removed and is now part of a building at 181 Ramsey Street. Doctor Potts succeeded Sperry and was attending Dustin when he died.

[4]Doctor Vicchers came a year previously. He married a Miss Coulter in Saint Paul. His widow married again and died in about 1912 at Fargo, N. D.

[5]She was returning home from the East where she had been at school. The clerk on the boat named Cochran did what he could for her until Saint Paul was reached. She was buried in the Mission Grounds (now Park Place).

[6]Fillmore was United States Commissioner of Pine Lands in Saint Paul.

[7]My mother was then sixteen years of age. She states that the day the man died, *Harpers Magazine* had just come; Thackeray's "The Virginians" was running in it and she did not get a chance to read it. Later in the year, my grandmother returned to Canada to bring the household goods here. She was taken ill with the cholera at Galena but recovered. Mrs. Armstrong, my mother, died in 1940 at the age of 102.

[8]This was the first time Miss Sherbourne met Doctor Brisbine. She later became his wife.

gather but a portion of the facts. During the year the Common Council passed bills incurred by the Board of Health amounting to $1,046.42, including the salary of $300 of the city physician. The above statements apply to the year 1854. I have several accounts of the disease which may have occurred either in 1854 or 1855, but in most instances the date cannot be definitely fixed. There is reason to believe, however, that the disease was more prevalent in 1855 but there are only two references to it in the newspapers of that year and none in the minutes of the City Council, no doubt for reasons previously stated.

Apparently the epidemic of 1854 caused the editor of the *Minnesota Democrat* to write an editorial on Health and Crowded Boats, the last paragraph of which is as follows: 'We do not wish to be misunderstood at a distance in making these remarks. *There is no sickness in Saint Paul now.* There has been very little on the river. We desire simply to secure the enforcement of proper sanitary regulations in the city and upon steamboats, for the protection of present and future residents and visitors either upon pleasure or business." This was in the issue of April 25, 1855. The warning evidently had its effect, for on May 1, the New City Council elected the following to serve on a Board of Health: P. R. Winne, L. C. Dunn, N. F. Masterson, Isaac Markley, A. H. Cavander, and D. A. Robertson. These men nominated Dr. Samuel Willey for city physician. The nomination was approved by the Council, which also passed a resolution thanking Doctor Goodrich for his previous services.

That the Board at once found work to do is evident, for the next day the following appeared in the *Democrat:*

"A young printer named Daniel E. Berry, from Harrisburg, Pennsylvania, died this morning at the hospital from cholera. Mr. B. came to Saint Paul yesterday on the Ben Bolt from Dubuque. When he was attacked by the cholera, he was turned out of the hotel . . . the sick man laid down on the pavement until his companion secured aid, when he was carried to Doctor Lambert's office, and thence to the hospital."

The editor's indignation at the inhumanity of the hotel keeper was no doubt intensified because Berry came to Saint Paul to work for the *Democrat* The other reference to cholera occurs in the same paper on May 9:

"We announce this evening with feelings of sincere regret the death of Mr. Platt, one of the editors and proprietors of *The Minnesotian.* Mr. Platt expired this morning at his residence in this city of cholera-morbus after an illness of thirty-eight hours . . ."

This was Henry P. Platt. Other sources of information leave no doubt that his demise was due to Asiatic cholera.

I shall now quote two or three interviews of the many I have had with old settlers, which illustrate the manner in which much of this material was obtained and how authenticated. In August, 1915, I had an interview with James Cody, then living on Smith Avenue near Ramsey Street. Cody was illiterate, but had a keen memory. That part of his statement relating to the cholera I give in his own words:

"I came to Saint Paul, May 1, 1854. The cholera was here at its worst in 1854 and 1855. Margaret, my sister, aged twenty-five, died of cholera at St. Joseph's Hospital May 1, 1855. James Farrell died the same week. In 1854, Fillmore went out for a drive into the country and came in and died. At the Cemetery at the Academy grounds (where St. Joseph's Academy now is) was a blackboard where the names of those dying of cholera were written. I counted thirty-four names in two weeks. On a raft on the river where the Wabasha bridge now is, a man died in a short time. In June, 1855, Andrew Welsh

died and willed all to wear a white scarf at his funeral. Dan Welsh died also; he was no relative to Andrew. The cholera was worse in 1855 than in 1854. Doctor Willey was the best doctor we had. Doctor Goodrich was a good doctor. Mary Anne Ireland, half sister to the Archbishop, recovered from the cholera in 1855. Of Tom Farrell's family, James died and Pat recovered. At St. Peter and Summit was a French Catholic Cemetery—a French woman was buried there in 1854. She had cholera. The funeral cost seventy dollars. Many cholera patients died at St. Joseph's Hospital. Bishop Cretin said a committee must help the Sisters, and the night my sister died, many were sick at the hospital. I helped there myself. Doctor Goodrich had charge of the cholera patients in 1854. Every boat that came brought in patients. James Farrell died at Tom Grace's near Park Place. Hannah McQuaid died about the same time at her home on Jackson Street, near Sherries. James Ryan died after breakfast at the same time. In May, Father Tom McManus gave a sermon about a man who brought him word of a sick man aboard the *War Eagle* (a steamboat). The sick man recovered, but the messenger died. Mike De Warn, his wife, and two daughters died of cholera on Eagle Street. ———— Kay, daughter and son, twenty-five and twenty-seven (years of age), were taken sick on Sunday evening and died the next day. Dennis Lynch was digging the cellar of the old Jackson Street Methodist Church and died two hours after. In 1854, Wm. Murnan died of cholera above Lake Pepin on a steamboat, and his brother John died later. I was to a dance on Second Street in 1855, five took it at the dance and three died—Wm. Ryan, Miss Flaherty and Ellen Burke. John Donley, in Reserve township, was taken ill while cutting hay in 1855. Mayor Knowl died at Sixth and Robert Streets in 1855."

I may say that the Dennis Lynch mentioned was the maternal grandfather of the late Thomas J. Maloney, who graduated in the same class as myself at the University of Minnesota. Doctor Maloney's mother confirmed Cody's statement. On July 31, 1915, Mr. Jacob Mathes said:

"I came to Saint Paul in 1852. I remember the cholera in Saint Paul. I can recollect the name of but one man who died of it here. He was a German named Hullsiek. I think it was probably about 1855. I was living in Cincinnati in 1849 and 1850 and also remember the cholera there. Coal fires were lighted at the street intersections as a preventative."

Both these statements are interesting as the German named Hullsiek was John Gabriel Hullsiek, aged twenty-six, the great uncle of the two Drs. Richard and Harold Hullsiek, now in Saint Paul. As to the bonfires on the street corners in Cincinnati I may say that it was a revival of the procedure adopted as a preventive for the bubonic plague in London two centuries before.[9] Mrs. W. D. Richardson told me that she was living in what is now Park Place in 1855. One evening a woman, who lived on what is now Smith, about opposite the Miller Hospital, came to her home and asked that she procure help as her husband was ill. Mr. Richardson was attending a Masonic meeting in the Mouzurkia Hall on St. Anthony and Exchange. Mrs. Richardson went after him. He brought a physician from the lodge meeting with him, but the man died. He was an engineer on one of the steamboats. Mrs. Richardson said that there were many cholera patients in Saint Paul, but this was the only one with whom she personally came in contact. She looked after the woman's baby until after the funeral. She stated that the Board of Health, the Masons, and the clergy cared for many patients. Mr. Richardson was one of the Masonic cholera relief committee.

That there was some cholera in St. Anthony is proved by an item in the minutes of the Board of County Commissioners for July 24, 1854.

"Wm. E———— (writing illegible) attending one cholera case at St. Anthony . . . $10.00. Same . . . attending one cholera case at St. Anthony . . . $10.00."

[9]It may be interesting to state here that the word "bonfire" was originally bonefire; that is, the fire in which the corpses of those who died of plague were cremated.

St. Anthony was part of Ramsey County until 1875. Mrs. Mary A. Fuller, who was Mrs. Samuel Willey, told me that one boat in 1855 brought in eleven cholera patients.[10] They were placed in wagons to be taken to St. Joseph's Hospital (which was in use in 1855). One of the wagons became mired and two patients died before it could be extricated. Mrs. Fuller (nee Irvine) came to Saint Paul as a child in 1843. It is unnecessary to multiply such accounts. Apparently there was little cholera after 1855, though Doctor Wharton told me he saw some patients on the river flats in 1857 or 1858.

In 1866, Saint Paul was again affected by the disease. The history of this outbreak has some amusing features. In April, the City Council ordered the city cleaned up in order to be prepared for a visitation of the disease, and at the same meeting a committee of the Council reported that the Pest House, located on the Poor Farm, had been sold with the rest of the farm and that they were endeavoring to secure a new site with the coöperation of the county. As will be seen, this complicated affairs. It was then discovered that no Board of Health or city physician existed, as none had been appointed since the new city administrators had come in. Thereupon, Dr. A. G. Brisbine was re-elected city physician and his salary fixed at $150.00 per year, a considerable reduction. The Board of Health was then organized with a clerk and a representative from each ward. The Board met on April 18, and set about taking steps to clean up the city as per order of the Council. Earlier in the month, a sanitary police system had been perfected and an order issued, with the acquiescence of the Council, that there be no dumping in the streets, undrained pools of stagnant water in streets and vacant lots should be drained or filled up, no hog pens or soap factories be allowed within the city limits, green hides must not be left on the sidewalks to perfume the air and refuse and garbage must be dumped in the river below the city limits. However, when health ordinances conflict with business interest, political policies often change. The dumping below the city limits was protested against by those handling refuse because of the extra haul, and those who took water from the river for sprinkling the streets joined them saying they were afraid the sprinkling water might be contaminated. The hog owners then protested, claiming that pig pasturing within the city did no harm and pigs acted as efficient scavengers. H. Rogers, who was in the hide business, stated that he had been in the leather trade in Philadelphia in 1832, and that there was no cholera among those in the leather business or even in the vicinity of the warehouses where hides and leather were stored and that such a business was a protection to those engaged in it and to those residing near such business houses. Mayor Prince then refused to sign the sanitary ordinances and the Council did not pass them over his veto. The editor of *The Pioneer,* in an editorial, thanked the Council for their action, stating that "when the hogs were driven out and the hides confined, he could not sleep because he missed the odor, but now that the fragrance was again restored he could secure his normal sleep." The Board of Health thereupon tendered their resignations, but they were not accepted. The members then, except the clerk who drew a salary, did not attend the meetings and practically no Board existed, as no quorum could be obtained. Finally, in June, the resignations were accepted, and in July, Dr. Thomas R. Potts, after some competition with Dr. C. D. Williams, was elected city physician and health

[10]In 1854, that portion of the city bounded by West Fourth Street, St. Peter Street, Pleasant Avenue, and West Ninth Street was swampy. A stream ran down Rice Street and through the grounds of St. Joseph's Hospital and reinforced by waters from springs along Pleasant Avenue there was enough water to turn the wheel of Irvine's Mill at West Third and Franklin Streets. The arched stone tailrace of this mill may still be seen east of the steps heading down the bluff at that point. When one said upper town, one referred to that part west of the swamp and centering about the seven corners, the approach to the upper levee being Eagle Street. Lower town was east of the swamp and corners on Jackson Street, which was the approach to the lower levee. It was in the road through this swamp that the wagon conveying the cholera patients was mired.

officer. In the meantime, the committee of the Council and the county commissioners could not agree and failed to provide a site for a hospital, but it was proposed to locate it in the third ward. This caused a panic in that part of town. A public meeting was then held and addresses were made by various citizens. Doctor Willey stated after the necessity for a cholera hospital had been admitted that "he thought St. Joseph's Hospital the best place; the city had had its cholera patients cared for there when the cholera was here before." Doctor Stewart also advocated this plan as "there was no time to build a cholera hospital and the cholera may break out any day. It had already appeared in Cincinnati and boats may bring it here any moment." Mr. Markoe offered to see what arrangements could be made for the reception of cholera patients at the hospital and report at a subsequent meeting. It was suggested also by Doctor Willey that daily reporting of cholera patients be required and reports of disease and mortality kept. This suggestion was taken up by the newly organized Board of Health and was the first ordinance of its kind in the state. This meeting was followed by a meeting at Timmes Grocery Store[11] of citizens who resided near the hospital and threats were made of burning the hospital if cholera patients were allowed there. It was then suggested that the Dakota House on the west side of the river be secured as a suitable place. Shortly after this meeting, I. P. Wright, chief health inspector, reported that he had rented the Dakota House on the west side of the river, but the residents of that locality had fiercely protested and Mr. Langevin, the owner, had begged him to give up the contract as he apprehended the hotel would be destroyed. So a site was secured at Kaposia. This again was given up for similar reasons. On August 21, the Board reported that they were building a quarantine station at Pig's Eye about a mile below Dayton's Bluff. "Two buildings, one 24 by 30 feet and another 30 by 30 feet, are almost completed, and bedding, stoves, furniture, and medicines will be sent down today." Boats coming up the river were to be required to stop there for inspection. On August 24, Dr. Charles E. Smith, a graduate of the University of Pennsylvania, who had just returned home after serving an internship at "Blockley," was made assistant to Doctor Potts, and placed in charge of the quarantine station. The two buildings cost $1400.

[11]At that time on the southwest corner of Tenth and St. Peter Streets.

(To be continued in February issue.)

Stephen H. Baxter, M.D.

President, Minnesota State Medical Association

President's Letter

A YEAR ago, a new president of our association took office only a few days after the treacherous Japanese attack on Pearl Harbor had precipitated a state of war. Before that attack, the United States was not at war with any nation; since then, our armed forces have been sent on missions of war to all parts of the world. Now, again, comes a change of administration, but it is in no sense a "change of horses in the midst of the stream." Responsibility for administration in our Association rests in a Council of members serving for overlapping terms, and representing every part of the state; but final authority rests in the truly representative House of Delegates. This mechanism provides a continuity of policy for the organization and gives to its elected leaders a sense of confidence and support which they as individuals could not possess. Without this support, any officers assuming positions of leadership in this year of grace, 1943, and approaching the problems with which they will be faced, must necessarily have many misgivings regarding their own adequacy; with it, they can go forward with confidence and assurance.

The nation is at war for its very life and every one of us has already felt the impact of the struggle. The war brings changes in the social and economic structure of the nation which vitally affect us all. Many of these changes will be permanent, for the old order will not return exactly as it was before the war. There are powerful forces at work which would destroy the practice of medicine as it is now conducted and would make the physician a hired employe of a bureaucracy. These forces should be and will be resisted, for experience has shown that scientific medicine reaches its highest development and accomplishes the greatest good for the greatest number of people under a free system unhampered by bureaucratic dictation.

Suppose, however, that the tide is irresistible, and fundamental and radical changes take place in the practice of medicine. The outlook could not be darker than was the outlook for Britain in 1940 when she was threatened with invasion and her cities were being bombed almost to complete destruction. During those darkest days, someone invented the slogan, "There will always be an England." The very repetition of that simple phrase engendered the faith that somehow it would come true, and inspired men to perform the works without which their faith would be dead.

If the threatened changes in medical practice become effective, will we be able to say "There will always be a medical profession?" True, there will always be physicians, for there will always be persons physically and mentally ill who will need the ministrations that only the physician can give, but there are many professions, each with its own ideals and code of ethics. My belief is that, regardless of the changes that may come in medical practice, there will always be a medical profession governed by the traditions of the profession and therefore essentially unchanged because those traditions are based upon principles which are fundamental to the character of the physician and to the best relationship between the physician and the patient. Our organization is one of the strongest forces contributing to the maintenance of that character and those principles, and it must be kept at the highest possible level of efficiency and influence.

With this inaugural expressing faith in the fundamentals of our profession and in the maintenance of its ideals, and with confidence in the future of medicine, the new administration assumes its duties.

Faith, to be vital and effective, must be implemented by works. The first of these works is to be found in the committee appointments. The work of many committees deals with scientific matters, the work of others deals with the relations of the medical profession to the public, and with matters affecting the economic aspects of medical practice. Both are important, and, in the final analysis, they both serve the same end which is to provide the best possible medical care through a well-trained and progressive medical profession. Practically every committee will be faced with problems which originate from, or are complicated by the state of war. The medical profession should take the lead in finding the solutions of these problems. Therefore the committees should attack them promptly and vigorously and have some concrete and well-considered recommendations to present to the annual convention to be held in Minneapolis in May.

President, Minnesota State Medical Association

Editorial

EARLY DAYS

WITH this issue Minnesota Medicine begins the twenty-sixth year of publication, It must be quite obvious to every member of the Minnesota State Medical Association that the judgment of the House of Delegates in 1917 was sound in principle and fraught with far-sighted wisdom. The journal had its inception with the appointment of a committee at the meeting of 1916, in Minneapolis. This committee consisted of Drs. R. J. Hill and J. Warren Little of Minneapolis, George E. Senkler and E. W. Buckley of Saint Paul, and C. L. Scofield of Benson, with instructions to determine the cost, the probable value of a journal to the society and to the profession as a whole, and to report at the next annual session.

At the 1917 meeting held in Saint Paul, a majority report was submitted, the substance of which was that owing to the existing state of war and the high cost of production it was deemed inadvisable at that time. A minority report submitted by Dr. E. W. Buckley of Saint Paul showing a most complete and careful study of the project was adopted by the House of Delegates. Following this, Doctor Buckley announced an offer of Ramsey County Society to present to the State Association the *Saint Paul Medical Journal* together with its advertising contracts and good will. This journal had had a successful career for seventeen years under the able editorship of Dr. Burnside Foster with Dr. H. Longstreet Taylor as business manager. The offer was promptly and gratefully accepted.

The first issue bearing the title of Minnesota Medicine went to the membership in January, 1918, and evoked many pleasing and gratifying comments. The *Journal of the American Medical Association* gave it a most complimentary editorial.

The first editor was Dr. E. T. F. Richards with Drs. R. E. Farr and J. E. Hynes of Minneapolis, E. W. Buckley and H. L. Taylor of Saint Paul and L. B. Wilson of Rochester constituting the first Editing and Publishing Committee. A contract had been entered into with the Bruce Publishing Company and to the credit of this company be it noted has been renewed at intervals ever since. Mr. J. R. Bruce, from the first issue, has shown a deep personal interest in the journal and frequently attends the meetings of the Editing and Publishing Committee, offering many valuable suggestions, and has in other ways been of inestimable value to the committee. The make-up and typographical work has been a delight to those who have learned to appreciate the fine touches of the printer's art. The artistic appearance of the journal bears testimony to the talent of Miss Olive Seibert, who for a number of years has been in charge of the make-up. In 1919 Dr. Richards resigned as editor and Dr. Carl B. Drake was appointed in his stead, and that he still retains the chair is ample evidence of his ability and perspicuity.

To Dr. John M. Armstrong who served as secretary of the Editing and Publishing Committee for several years and for his valuable contributions to the History of Medicine in Minnesota the Association is profoundly grateful, and to all those who have served and given of their time and talents to so worthy a cause the Association is indebted to a greater degree than they can possibly appreciate.

With the passing of the years we feel assured that Minnesota Medicine will go on to greater fields of usefulness to the State Association and to the profession at large. To the present staff we extend our congratulations and hopes for the future.

J. T. Christison.

GREETINGS FROM THE MEDICAL SCHOOL

THE Medical School of the University of Minnesota is pleased to extend most cordial greetings to Minnesota Medicine on its twenty-fifth birthday. This has been a most significant quarter century in the development of medical education in Minnesota.

From the date of its official opening in 1888, the Medical School of our State University has

enjoyed and profited by the interest and loyal support of the physicians of the state. There were, at times, natural differences of opinion, particularly in the days of the reorganization and expansion of the school, but never was there any fundamental question about the determination of the physicians of this state to have a Medical School of which they could justifiably be proud.

During the past quarter century the Medical School has been able to expand its laboratory and clinical facilities and to enlarge and strengthen its teaching and research staffs. Special gifts have provided clinical, teaching and research units such as the George Chase Christian Memorial Cancer Institute; the Todd Eye, Ear, Nose and Throat Hospital; the Eustis Hospital for Crippled Children; the Psychiatric Clinic for Children, and the Department of Postgraduate Medical Instruction. This latter, which has been conducted in coöperation with the University's Center for Continuation Study, has been a unique and most successful service to the physicians of this state.

Prominent among the responsibilities of a modern Medical School is the conduct of scientific research. To support such research at the University of Minnesota, the State Medical Association joined with the Regents of the University in a request to the legislature for a special appropriation for medical research. This appropriation, which was first voted in 1919 and has been continued annually, has been invaluable in supporting medical research, some of which has resulted in important progress in medical practice and has brought credit to the University and to the state of Minnesota.

In promoting the relationship of the Medical School to the profession of the state, Minnesota Medicine has rendered effective and valuable service. At the present time, the Medical School is concentrating its efforts primarily on war research and on the training of medical students for service with the armed forces in a minimum possible time. During these critical times it is especially important that the Medical School and the profession of the state coöperate most intimately in keeping medicine in Minnesota upon a sound and progressive course. In the attainment of this objective Minnesota Medicine will continue to play an exceedingly important role.

Harold S. Diehl.

TWENTY-FIVE YEARS HAVE PASSED

TWENTY-FIVE years have passed since the first number of Minnesota Medicine appeared in January, 1918. It seems advisable, therefore, to commemorate the occasion by the publication of a special number of the journal devoted to a review of the scientific progress made in medicine during this period. All of the articles in this number were submitted at our request and most of them record the development of the various specialties during this period. A complete portrayal of progress is impossible. The attempt to cover most of the specialties was not entirely successful. We trust that the summary, though incomplete, will prove interesting to our readers.

Minnesota Medicine had its beginning during the last year of World War I. A number of its editorials during its first year consisted of pleas for more enlistments in the Medical Reserve Corps. By June, 1918—fourteen months after our entrance into the war—there were only 15,000 medical men in the service compared to some 40,000 now in the service. Some of the editorials which have appeared the past year resemble those of twenty-five years ago on the same subject of enlistment. Many of the authors who appeared in the first volume are still contributors—evidence that twenty-five years is not such a long period of time after all.

Any success that the journal may have attained is due to the coöperation of the profession of the state. The character of the scientific papers which have appeared in Minnesota Medicine affords some idea of the progress made in medical science during the past twenty-five years. Members have been most coöperative in furnishing editorials when asked. Many members have assisted in the editing of the journal from time to time, in obtaining reviews of articles in the former Progress Section, in writing book reviews and as committee chairmen in furnishing sections such as those of Medical Economics and Industrial Health. No attempt will be made to name them, but they have all made valuable contributions.

The purposes of the journal as outlined in its first editorial were those of the State Medical Association:

To federate and bring into one compact organization the entire medical profession of the State of Minnesota;

To extend medical knowledge and advance medical science;

To elevate the standard of medical education;

To secure the enactment and enforcement of just medical laws;

To promote friendly intercourse among physicians;

To enlighten and direct public opinion in regard to the great problems of state medicine. . . .

The policy of the journal as asserted in its first number was to remain independent, not to be the mouthpiece of any individual or any group and to work only for the best interests of the profession and the public. Advertising was to comply strictly with rules laid down by the Council on Pharmacy and Chemistry of the American Medical Association.

This has been, and continues to be, the aim of the journal. The goal may not have been fully reached but we shall press on with the same purposes in mind.

IMPROVEMENT IN MORTALITY STATISTICS

THAT progress has been made during the past twenty-five years in medicine and in public health is shown by mortality statistics. The experience of the Metropolitan Life Insurance Company,* which closely parallels the vital statistics of the country at large, shows some interesting data.

Deaths from tuberculosis are today about one-fifth of those twenty-five years ago. Measles, scarlet fever, whooping cough, diphtheria, the diarrheas and enteritis have been virtually eliminated as causes of death today. Interesting in this connection are the vital statistics for 1939 in regard to whooping cough, measles and diphtheria. In that year there were 3,026 deaths in the country attributed to whooping cough, 1,174 to measles and 1,993 to diphtheria. While not nearly as serious causes of death in comparison with twenty-five years ago, the statement that these three diseases have been virtually eliminated as causes of death should be somewhat modified.

The mortality of syphilis is today about half of that twenty-five years ago. That from pneumonia has been at least halved. Maternal deaths today are also about half the figure of twenty-five years ago.

The reduction in fatalities due to industry has been outstanding during this period. By contrast the fatalities due to automobile accidents have greatly increased. This perhaps is not surprising when we consider that in 1917 there were only five million automobiles on the roads compared with thirty-three million before gas and tire rationing came into effect. Rationing and a thirty-five-mile speed limit should have a favorable effect on this figure.

*Bulletin of the Metropolitan Life Insurance Company, 23:1, (Mar.) 1942.

THE INCIDENCE OF SYPHILIS

A FEW years ago when venereal disease was brought more into the open and an active campaign to attack the problem was instituted, some assertions were made as to the incidence of venereal disease which at the time were questionable. If our memory serves us correctly we were led to believe that about every tenth individual had, had had, or would have syphilis. To those clinicians in the Twin Cities who were on the lookout for cases of primary syphilis for use as clinical material, this statement certainly did not seem true for Minnesota.

It is, therefore, most interesting to have presented an analysis of the incidence of syphilis as discovered amongst some 1,895,778 selectees and volunteers examined up to August 31, 1941.* The reports on this number are sufficiently complete to warrant analysis and have come from every state in the union except Idaho, Kentucky, Oregon and Vermont.

In brief, 45.3 per 1000 of selectees between the ages of twenty-one and thirty-five in the entire country showed positive or doubtful blood reactions.

Broken down, the figures show an incidence of 17.4 per 1,000 in the white selectees in this age group and 252.3 in the colored.

It is interesting to note how Minnesota stands in relation to the other states. We rank forty-first out of forty-five states listed and have an incidence of 8.6 per 1000 whites in this age group. We also stand thirty-fifth in the thirty-seven states tabulated for negro selectees.

Among white young men in Minnesota between the ages of twenty-one and thirty-five less than 1 per cent have positive blood reactions. While the incidence, according to this article, tends to increase slightly in the older age groups, the incidence in the male white population is probably less than 1 per cent.

*Vonderlehr, R. A., and Usilton, Lida J.: Syphilis among men of draft age in the United States. Jour. A.M.A., 120: 1369, (Dec. 26) 1942.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

"DOCTOR-SHORTAGE"

The phrase "doctor-shortage" is on every editor's mind these days. It has become one of those accepted feature subjects which every publication feels it must cover for its readers. Generally the author is a lay "viewer-with-alarm" or a staff feature writer and seldom, if ever, one of the medical men who have personally struggled with the problem of procuring physicians for the armed forces.

To the latter was given the job of finding and classifying the men who could be spared from their communities for the expanding army. Their job was tremendous; but the anniversary of Pearl Harbor found most of the states with quotas met or exceeded and an orderly procedure established.

That there would be some hardship was a mathematical certainty. That the medical situation in some industrial areas might become acute in spite of every recourse open to Procurement and Assignment was also clearly foreseen.

Procurement's War Job

The point was that there is a war and Procurement and Assignment had a war job to do. The fighting forces had to have doctors and PAS found the doctors. They were also mindful of the need at home and saw to it, in so far as they were able, under the law, that no community was completely stripped of medical service. The need was urgent, the work had to be done quickly; but the problem of medical distribution at home was neither ignored nor overlooked.

Now it has become apparent, even to the casual observer, that the boom towns have medical as well as housing, sanitation and police problems. It is a curious fact, however, that lack of housing and sanitary facilities is accepted with philosophical resignation by Congress and the press. Everybody recognizes that war and not the architects or the lumber dealers or the plumbers are to blame for it. There seems to be little justice or understanding, therefore, in the general disposition to blame the doctors for the inevitable reduction in the number available for medical services in these areas.

Juggling the Bureaus

The critics who demand new agencies and new laws forget that no matter how they juggle the bureaus they will still be dealing with a limited number of men and men who have the same right of preference about where they will work as the welders and riveters. The proposal to lower license standards for the duration of the war might indeed be the answer in exceptional instances; but the general assumption that a poorly trained physician is better than none at all is open to argument even in wartime and the difficulty of revoking special wartime licenses when the war is over must be considered.

The logical answer to the problem has already been made in many isolated communities throughout the country and is being encouraged and implemented on the basis of careful studies by Procurement and Assignment. That is an effective reorganization of the time and services of the doctors who remain at home.

Portland's Answer

That is what physicians of Portland, Oregon, have done, for example, in dealing with the medical problems of the Kaiser plants which in themselves created a monster boom town problem on the Pacific coast. If it could be done there without forced relocation of physicians and sacrifice of licensing standards, it can be done elsewhere. State Committees of Procurement and Assignment are now not merely combing their lists for men who can be spared to fill Army quotas

for 1943 but are carefully studying the civilian situation in their states with a view to just such local readjustments and reorganizations.

Rotation for Rural Communities

In Minnesota the largest concentrations of industrial workers are near the Twin Cities and they are served by the largest concentrations of physicians and hospitals in the state. Consequently there are no typical boom town problems in Minnesota. The greatest difficulty will come in rural areas, now largely drained of all but the minimum number essential for their districts. Those who remain will undoubtedly be operating in the future on a coöperative, rotating basis by which responsibilities for serving some areas will be assumed jointly by all neighboring physicians. Such coöperation has worked admirably where it has been tried and will meet the need more satisfactorily than any hasty licensing of doubtfully trained men.

RHODE ISLAND'S SICK BENEFIT PLAN—FIRST IN U. S.

The first sickness compensation plan to be attempted in any state in the United States goes into effect in Rhode Island this month.

According to an article by John E. Farrell, executive secretary of the Rhode Island Medical Association, which appeared in a recent issue of the *Rhode Island Medical Journal*, the actual background of the act was not employe demand but the fact that a reserve fund of approximately twenty-eight million dollars has been amassed by the state as a result of unemployment compensation taxes. The Unemployment Compensation Board proposed sickness compensation to forestall any demand on the part of employes to eliminate or reduce their tax.

Rhode Island is one of only five states in the country in which employes contribute to unemployment compensation insurance. The three per cent taken from employe wages for this purpose in a highly industrialized state has run into a tidy sum, sufficient to start the sickness compensation plan on a financially sound basis. Moreover, employes are already being taxed one and one-half per cent in addition to pay for the new plan, the entire sickness tax being deducted from employe contributions.

Sizable Reserve

Actually payroll deductions have been made since last June and a sizable fund is in process of accumulation from which benefits will be paid after April 1, 1943.

Labor leaders are reported to have endorsed the plan and it has the blessing and actual support of the Federal Social Security Board. Physicians, upon whom rests the burden of certifying claimants for benefits, were not consulted and they face many vexing problems.

The definition of sickness is very broad in the act. It carries a possibility of certification by other licensed healers besides doctors of medicine and of many questionable claims. The doctor will be placed between the authorities on the one hand, the patient on the other and thus runs the risk of endangering his reputation for integrity or of losing patients.

The solution for this problem suggested by Mr. Farrell is the employment of a qualified medical man by the disbursing agency to certify all claims. This solution is in line with recommendations by the House of Delegates of the American Medical Association.

Federal Government Interested

Most interesting of Mr. Farrell's observations is the close intimate connection which even now exists, he notes, between the Federal Security Agency and the Rhode Island plan. It is provided in the act that any funds which may be made available under title III of the Social Security Act shall be used for administration of the plan. The plan also calls for utilization of present public employment offices throughout the state as administrative offices for the cash sickness compensation fund and such offices are now supported in part by federal funds.

For Local Control

Says Mr. Farrell in conclusion: "Whatever the outcome of the present experiment, it is evident that Rhode Island has a tremendous responsibility to prove that its sickness insurance plan can be carried forward successfully under local control and with local finances."

Rhode Island and other states with sound financial reserves may find it possible to administer sickness insurance successfully. Success will invite imitation elsewhere and it is apparent that federal authorities anticipate eventual participation in administrative control.

INSURING AGAINST THE "THIRD HAZARD"

Most discussions about health insurance are carried on either by professed advocates of government participation or by representatives of the medical profession who, in spite of every wish to be impartial, may be regarded as fundamentally opposed, in general, to plans for socialization of medicine.

It is, therefore, of real interest to have an analysis of the outlook for health insurance in America by a neutral like Mr. Reinhard A. Hohaus of New York who can talk about it without prejudice in relation to the general plan for social security in America.

Mr. Hohaus is an actuary for the Metropolitan Life Insurance Company. He finds that Social Security provisions for old age and for dependent survivors have made a good start along sound lines. On the other hand, basic changes in principle and underlying philosophy are essential to the present plan for unemployment insurance and these should come about before the postwar depression arrives, though the outlook for such developments is not encouraging.

Going Will Be Difficult

Health insurance, he catalogues as the third possible category if the government is to protect against the major hazards of life. But, here, the going will be difficult; the country is unexplored and he earnestly advises against any blind following of precedents for government old age, survivorship and unemployment insurance plans or of government plans adopted abroad.

The situation is confused, the questions to be answered many and even the meaning of the term "health insurance" yet to be determined. Furthermore, health insurance does not, like old-age insurance, permit provision of a basic amount of service on a minimum "social adequacy" level which the citizen may supplement with his own protection. It is highly inadvisable to foster the existence of overlapping systems of care with several doctors replacing one responsible advisor for the individual beneficiary. Also compensation for time lost by reason of illness is regarded by many as of equal importance to insurance for medical services; but the one does not dovetail successfully with the other.

Preventive Medicine Susceptible

The preventive aspect of medicine seems to Mr. Hohaus to be much more susceptible of governmental action than personal medical service. In its more elementary phases including sanitation and epidemic control it is now part of the normal activities of public health authorities. He sees no insuperable obstacle to including more positive functions of maintaining health and well-being at a high level of efficiency, including in these functions, nutrition education and recreation and physical training, no less than immunization and a yearly check-up. "Here, if anywhere," he says, "government does not need to be too meticulous about drawing a line between what is merely adequate and what may be described as additional or supplementary. Positive health promotion of a public or community nature is one field in which an intelligent and non-overlapping mutually beneficial rivalry between government and private enterprise is entirely practicable and of inestimable advantage to all.

Harassed Patient

"New problems arise," he remarks, "if government decides to extend social insurance to the field of health benefits and we are to retain our democrative principle of giving individuals the opportunity of buying additional protection from private sources through their private means. These problems would indicate that, in many cases at least, the function of private health insurance and private medical care should be in the nature of an alternative method of providing the entire coverage which individuals or groups may elect under prescribed conditions, rather than just additional coverage to supplement the basic minimum protection otherwise offered by social insurance. Supplementary medical care, carrying on where the compulsory minimum provisions leave off, would surely often complicate matters and unnecessarily harass the patient by subjecting him to a switch from one system to the other, perhaps at the very time he most needs continuity of treatment. What the effect would be on the quality and effectiveness of the medical treatment is a question for a physician to answer, but I suspect the answer would be far from favorable. When a physician knows that his primary responsibility for a certain case is limited in time or extent or shared contemporaneously with some other physician or physicians, should

we expect his sense of responsibility, of independence and of initiative in the case, or his personal relationship to the patient to be keyed to as high a pitch as it otherwise might?"

Innovations Ahead

On the other hand, Mr. Hohaus, in common with other observers, sees ahead indications of major innovations in medical services.

"The questions posed," he says, "are not simply the pros and cons of extending our present social insurance system to health insurance. A number of signs indicate that, irrespective of what the decision is regarding such an extension, the next few years will see a number of major developments and innovations in the provision of medical care. We are told that about one-third of American doctors and dentists will be in the armed forces by the end of this year. Similar reductions in the civilian supply of nurses and other personnel auxiliary to the medical profession must be expected. . . . Can we safely assume that all temporary measures which may be required because of such shortages will disappear when the war ends? May we not anticipate that experience will show that at least some should be retained permanently?

"Then, too, there will be the exposure of a very large part of the medical profession—especially physicians who have gone from internship to the armed forces—to methods of medical care quite dissimilar in economic and other aspects from the conventional methods of private practice in peacetime. What will their attitude be after peace is won and they and others in military and naval service return to civilian life?"

Modifications Will Be Required

If the broad concept that a minimum of social protection against the hazards of life should be governmentally provided is extended to include medical services, Mr. Hohaus is certain that modifications will be required because of the intimate and personal nature of the services. Here, he says, the role of the Federal government must be one of greater aloofness, confined to assuring that adequate care will be provided, rather than directly participating in the actual provision. Such direct participation would be appropriate only when no suitable agency appears to be available and where choice would seem to lie between a bare minimum governmentally provided and outright charity, or nothing at all.

In Memoriam

WILLIAM ANDREW LEE

Dr. William A. Lee, a practitioner at Fergus Falls since 1919, died November 22, 1942, at the age of sixty-three.

Born at Casey, Illinois, October 3, 1879, Dr. Lee attended Central Normal College at Danville, Indiana, where he received a B.S. degree in 1902. He received his medical education at Northwestern Medical School, Chicago, receiving his medical degree in 1911. The following year he served as intern at Mercy Hospital in Davenport, Iowa.

Dr. Lee practiced at Underwood, Minnesota, from 1912 until he entered the army in 1917. After serving eighteen months, part of that time overseas, he joined the medical group with Drs. Baker and Burnap in Fergus Falls. In 1921 he opened an office for himself which he maintained until July, 1942. Because of failing health he then returned to the Fergus Falls Clinic.

He served as city health physician for a great many years and as Otter Tail County coroner for several terms. He was a member of the Elks and Masonic Lodges, a trustee of the Methodist Church, a past Commander of the American Legion and a member of the executive committee of the Boy Scouts for many years. He always took a deep interest in young people and was at one time a teacher and worker in the Methodist Sunday School.

In 1922 Dr. Lee married Lucy Logan Moses of Fergus Falls, who with a son Gordon and daughter Marcella, survives him.

Perhaps Dr. Lee's outstanding characteristic was his cheerfulness which never deserted him even in financial or physical distress. He was also modest but capable in his chosen calling. It is not surprising he had as a result a host of friends. His life is typified by the following tribute to—

The Family Doctor

He walked with modest mien and kindly eye
Along the street, and few would ever guess
That mid the hurrying throngs that surged and pressed
A master soul had passed them gently by.
His smile was such that little children hied
To bask them in its genial wholesomeness;
And when he spake, his words of cheeriness
Shed welcome sunshine like a spring noon sky.
A simple man, yet none in all the land
More great. For he was ever found apart
Where beds of human suffering grimly stand;
And there with soul alert, he lived his art—
The tender gift of healing in his hand,
And God's sweet law of service in his heart.

INDUSTRIAL HEALTH

Edited by the Committee on Industrial Health and Occupational Diseases

FOR WORKER HEALTH AND MORALE

Four hundred health directors of leading industrial concerns met recently in Pittsburgh under auspices of the Industrial Hygiene Foundation and seriously discussed a variety of plans for improving the health of their employes.

No longer may employers think only in terms of workmen's compensation. They must also consider good nutrition, morale and adequate medical services, according to these pioneers in better worker health.

Lost time for injuries and illnesses of a non-industrial origin costs the war effort 2,500,000 man-days per week according to the Foundation's council, T. C. Waters of Baltimore. To be successful in the future, Mr. Waters informed the meeting, business enterprise must and will assume more legal responsibility for the health, not only of the workers, but of their families.

Absenteeism Serious

A statistical survey of fourteen industries in 1941 showed 83.1 cases of abstenteeism per 1,000 male workers for eight days or longer; 104.6 cases per 1,000 female workers.

One of the remedies discussed at length by these employers and their health directors was to see that the employe is put on the job to which he is best adapted. "Getting fed up" has considerable to do with absenteeism and ineffectiveness. A management policy which shows its appreciation of the workers' efforts and which provides good physical working conditions was regarded as highly important to worker morale and health.

Food and Production

Periodic physical examinations, diet education and correction (especially among women employes from eighteen to twenty-four) are new to many executives but were regarded by these men as fundamental to an adequate plant health program. The exact relationship of diet to fatigue has not yet been satisfactorily solved; but practical experience in many plants has shown the great value of between-meal refreshments of something other than candy and soft drinks. Milk, soups, sandwiches, fruit have all been used with good effect.

At the meeting, War Manpower Chief Paul V. McNutt predicted that by the end of the year the nation's total labor force will be 59,000,000 of whom 18,000,000 will be in war-production jobs—more than twice as many as a year ago. If the war continues the war-production force will expand to 30,000,000 by the end of 1943.

Services Must Be Pooled

Safeguarding this great army of workers will require all of the ingenuity and coöperative effort of doctors and employers. Physicians whose practices have been limited, heretofore, to industry will need the aid of every other practitioner in industrial communities to cut down absences from illness and protect the workers' families. Pooling of medical services, hospital facilities and nurses will be necessary where war requirements have expanded populations and normal facilities will otherwise break down.

It is obvious that interest in worker health is no longer confined to physicians and health authorities. Employers and business organizations are rapidly awakening to its significance in terms of production and physicians must be ready to respond to that interest.

Employers Adjust Sights

It is also significant that publications devoted to the business and production outlook are now giving space to meetings such as the one held in Pittsburgh. According to *Business Week,* commenting on the matter, employers need to revise their points of view. The editors prophesy that many will be adjusting their sights soon to health insurance plans, with the cost shared by the worker. The fact is that industrial medical services on the insurance plan are not new in the United States, and may be feasible in a few industrial communities. Workers and their families in most cases, however, must depend upon private medical services.

Twenty-five Years Ago

January, 1918

Governor J. A. A. Burnquist has made the following appointments on the State Board of Health to take effect January 17, 1918: Dr. George D. Head, Minneapolis; Dr. Neill M. Watson, Red Lake Falls; Dr. R. C. Hunt, Fairmont.

Governor J. A. A. Burnquist has appointed Dr. C. W. More of Eveleth on the Advisory Commission of the State Sanatorium for Consumptives (*sic*). Dr. H. Longstreet Taylor, whose term expired, has served on the Advisory Commission as its president since the Commission was created by the Legislature in 1903. Dr. Taylor has always been an enthusiast in anti-tuberculosis work. He has been instrumental in establishing fifteen public, one charitable and one private institution and has seen almost 1500 beds dedicated to the consumptive (*sic*) population of Minnesota during his term of office.

February, 1918

Dr. W. A. Coventry of Duluth read a paper on "Toxemias of Pregnancy" at the midwinter meeting of the Upper Mississippi Medical Society held at Brainerd, January 8. Dr. Thomas McDavitt, secretary of the State Association, also spoke on the defense work of the State Association.

Dr. S. S. Shannon, formerly of Barnum, has located at Crosby. He is associated with Drs. B. A. Smith, E. J. Pengelly, and George Gilbert in the Miners Hospital.

At the December, 1917, meeting of the Red River Valley Medical Society, the following officers were elected: President, Dr. H. W. Froehlich, Thief River Falls; vice president, Dr. F. M. Dryden, Crookston; secretary-treasurer, Dr. Ralph L. Kirsch, Crookston.

March, 1918

Captain Ralph St. J. Perry has been placed in charge of the examination of applicants for commissions in the Medical Reserve Corps from the Northwest.

The tuberculosis sanitarium erected just south of Thief River Falls by the counties of Pennington, Marshall, and Roseau, was formally opened to the public on December 31, 1917. The principal address was delivered by Hon. George F. Mathson of Roseau County. Dr. Robinson Bosworth, executive officer of the Sanitarium Commission of the State Board of Control, was present and spoke briefly. The speaker and commissioner referred often to Dr. G. S. Wattam of Warren, to whose work in behalf of tuberculous patients the people of the state owe a great deal.

April, 1918

Naval Station Hospital, Unit No. 10, has been formed in Minneapolis with the following personnel: Clifford E. Henry, grade of surgeon, rank of Lieutenant Commander; Clinton C. Tyrrell, grade of surgeon, rank of Lieutenant Commander; John T. Litchfield, grade of passed assistant surgeon, rank of Lieutenant; J. Arthur Riegel, grade assistant surgeon, rank of Lieutenant (j.g.); William P. Robertson, grade of assistant surgeon, rank of Lieutenant (j.g.).

Dr. J. M. Conroy, late of the City and County Hospital, Saint Paul, has been appointed medical superintendent of Nopeming Sanatorium, near Duluth, Minnesota, to serve during the absence in France of Dr. A. T. Laird.

The following members of the St. Louis County Medical Society have been appointed as the Committee on Arrangements for the next meeting of the Minnesota State Medical Association to be held in Duluth, August 28, 29 and 30: Dr. C. F. McComb, chairman; Dr. W. H. Magie, Dr. W. R. Bagley, Dr. A. H. Schwartz, Dr. C. L. Haney.

May, 1918

Lieut. John S. Abbott, M.R.C., attached to the 18th F.A.B.E.F., is reported in the casualty list of April 15, as missing in action. Dr. Abbott, a practicing surgeon of Saint Paul, received his commission early in June, 1917, and immediately left for France, assigned to the British forces. (Later it was reported that he was a prisoner in Germany.)

The success of Clinical Week under the management of the Hennepin County Medical Society, has been such as to insure that it will be made an annual affair in Minneapolis. Almost 400 physicians from outside the city attended.

Major C. H. Mayo returned April 12 after three weeks' absence in Washington, Fort Oglethorpe and New York.

Major W. J. Mayo departed April 13 for Washington to be absent about three weeks.

June, 1918

Dr. E. W. Buckley, Medical Director of the Knights of Columbus, will leave for France, June 1, to supervise the opening of K. C. huts in the American Army camps in France, England, Ireland and Italy.

Dr. Paul J. Preston writes from Italy thanking the management of Minnesota Medicine for sending the journal to him.

Major L. B. Wilson, Director of the Division of Pathology, Mayo Clinic, and Director of the Field Army Medical Museum, is in France.

The librarians of the Hennepin and Ramsey County Medical Societies will meet in the near future to arrange the distribution of the exchanges of Minnesota Medicine in accordance with action taken by the Publication Committee.

The following physicians from Minnesota attended the meeting of the medical section of the National Council for Defense at Washington, D. C., May 4 and 5: Dr. W. H. Magie, Duluth; Dr. W. L. Palmer, Al-

bert Lea; Dr. H. M. Workman, Tracy; Dr. J. W. Little, Minneapolis; Dr. Thomas McDavitt, Saint Paul; Dr. H. P. Ritchie, Saint Paul, and Dr. H. L. Taylor, Saint Paul.

July, 1918

Lieut. Theodore H. Sweetser of Minneapolis has been recommended for the British War Cross for bravery and devotion to duty near Passchendaele on March 13. Though suffering from poison gas, he helped rescue men from a destroyed dugout.

Dean Wulling and his co-workers in the College of Pharmacy, University of Minnesota, during the past year prepared 28,000 half pint bottles of tincture of digitalis. This constitutes the complete supply of the drug used in the United States Army. A large part of the drug was raised in the medical garden of the college.

Word has been received from Major J. S. White of Saint Paul of his safe arrival overseas. (He was later promoted to rank of Lieutenant-Colonel.)

August, 1918

Dr. Alexander R. Colvin of Saint Paul has been commissioned a major in the medical reserve corps.

Dr. Ernest T. F. Richards, Saint Paul, has been appointed Acting Chief of the Department of Medicine, University of Minnesota, during the absence of Dr. L. G. Rowntree, who has been commissioned a lieutenant-colonel in the national Army.

Thirteen University of Minnesota Medical School seniors, on their way to France, received their diplomas aboard ship. They are members of Base Hospital, Unit No. 26, and were the first class from the University to get their collegiate degrees on the high seas.

A dispatch from the Associated Press announces under date of July 18 that the government is about to assume control of the entire medical profession in the United States to obtain sufficient doctors for the fast growing Army, and at the same time to distribute those remaining to the localities or services where they are most needed for civilian work.

At its regular meeting, July 9, the State Board of Health created a Division of Child Conservation (later changed to Division of Child Welfare), and appointed Dr. E. J. Huenekens of Minneapolis as director. Two nurses, who are experienced in public health work, have been employed by the Board for field work in this division.

September, 1918

Word comes to us that Lieut. Stanley R. Maxeiner of Minneapolis, who has been with the British Expeditionary Forces for the past year, has devised a splint for the temporary care of fracture of the humerus, et cetera.

Dr. P. M. Hall of Minneapolis took Dr. George W. Beach's place as superintendent of the State Tuberculosis Sanatorium at Walker, August 1.

October, 1918

At the annual meeting of the Minnesota State Medical Association held at Duluth, August 28, 29 and 30, Major John D. McLean, secretary of the general medical board of the National Council of Defense, was one of the principal speakers . . . His subject was "Medical Reserve Corps and Volunteer Service Corps." . . . Col. Reuben Miller of the Surgeon General's office decribed conditions that obtain in the Army for medical men.

Lieut. R. C. Lowe of Fairmont, Minnesota, who has been at home on leave, has been appointed a flight surgeon and hereafter will devote his time to caring for Uncle Sam's fliers. He is now stationed at Wilbur Wright Field, Dayton, Ohio.

The present address of Captain Stephen H. Baxter, M.R.C., Minneapolis, is 60th Infantry, A.E.F., France.

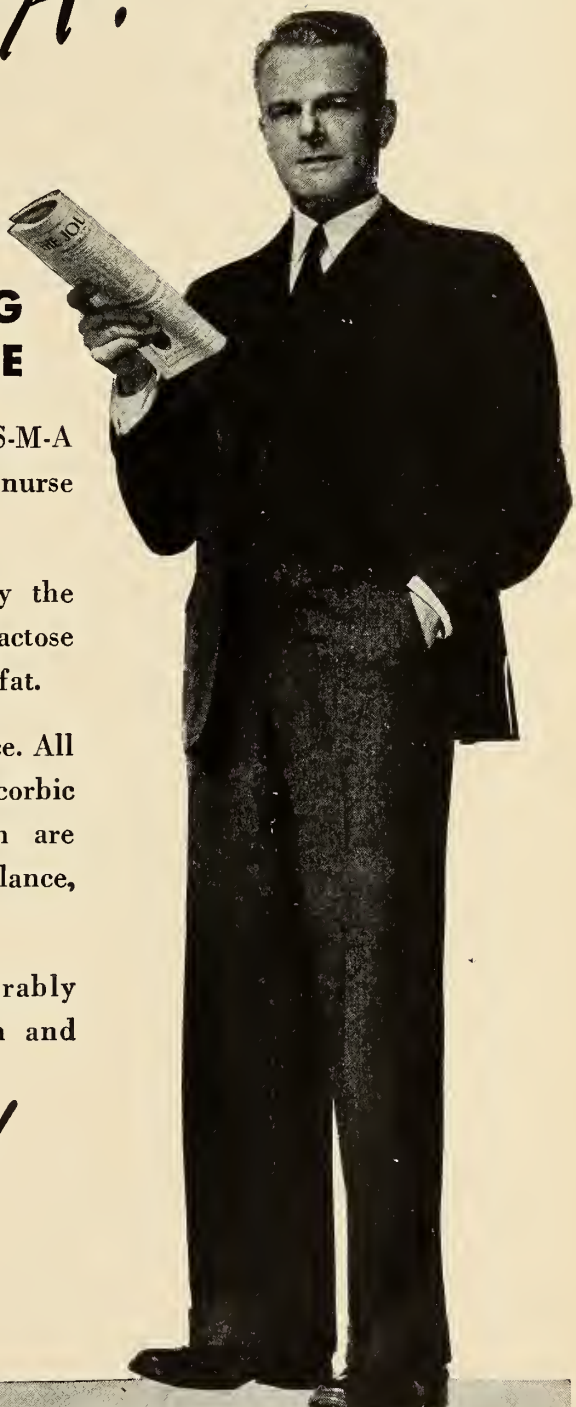
November, 1918

Dr. Nellie Barsness, the first woman physician in Saint Paul appointed to overseas war service, left for New York . . . expecting to sail at once for France, where she will serve in the new hospital for the treatment of gassed soldiers established by the American Women's Suffrage Association.

Lieut. Felix John Traxler and Miss Marie Fitzgerald were married at San Antonio, Texas, on August 31. Lieutenant Traxler is a graduate of Creighton University and up to the time of his entering the service practiced at Henderson, Minnesota.

December, 1918

Dr. Henry Wireman Cook, Minneapolis, has been called to Washington to serve for six months as associate director of the Medical Service Bureau of the American Red Cross.



Dr. F. C. Rodda of Minneapolis left a few weeks ago for New York, expecting to leave soon for France where he will take up Red Cross work in children's hospitals behind the battle lines.

Owing to the epidemic of influenza and to the great number of physicians in service the executive committee of the Southern Minnesota Medical Association decided not to hold their annual session as planned on November 25 and 26.

Dr. E. M. Jones, Saint Paul, now stationed at Walter Reed Hospital, Washington, D. C., has recently been promoted to the rank of major.

*I like S-M-A!**

IN INFANT FEEDING ...IT SAVES MY TIME

- Directions on how to mix and feed S-M-A can be explained to the mother and nurse in two minutes.
- S-M-A is more easily digested by the normal infant because of the all-lactose carbohydrate and the unique S-M-A fat.
- With S-M-A nothing is left to chance. All the vitamin requirements, except ascorbic acid, together with additional iron are included in S-M-A in the proper balance, ready to feed.
- S-M-A fed infants compare favorably with breast-fed infants in growth and development.

MEDICAL BROADCAST FOR JANUARY

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Saturday morning over Station WCCO, Minneapolis and Saint Paul, and at 11:30 o'clock over Station WLB, University of Minnesota. Speaker: William A. O'Brien, M.D., Director of Postgraduate Medical Education, Medical School, University of Minnesota.

January 2—Blood and Blood Substitutes
January 9—Hemorrhage and Shock
January 16—Treatment of Burns
January 23—Blood and Blood Substitutes in Chronic Illness
January 30—Bleeding Gums

CONGRESS ON INDUSTRIAL HEALTH

The fifth annual Congress on Industrial Health, sponsored by the Council on Industrial Health of the A.M.A., will be held on Monday, Tuesday and Wednesday, January 11-13, 1943, at the Palmer House in Chicago. These meetings are open to physicians and others interested in industrial health. Various phases having to do with prevention and treatment of diseases and conditions associated with industry will be participated in by the Council on Pharmacy and Chemistry and the various sub-committees of the Council on Industrial Health. On the last day Nutrition of Industrial Workers will be the subject of a round-table discussion to be followed by a conference on industrial health under the joint auspices of the Chicago Medical Society and the Illinois Manufacturers Association.

UROLOGY AWARD

The American Urological Association offers an annual award "not to exceed $500" for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented, and if the Committee on Scientific Research deem none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years.

The selected essay (or essays) will appear on the program of the forthcoming meeting of the American

Urological Association, May 31-June 3, 1943, Hotel Jefferson, St. Louis, Missouri.

Essays must be in the hands of the Secretary, Dr. Thomas D. Moore, 89 Madison Avenue, Memphis, Tennessee, on or before March 1, 1943.

WAR SURGERY MEETING

To fill the need for inspiration and information with regard to the war medical problem, the American Academy of Orthopedic Surgeons and the Clinical Orthopedic Society have combined their annual meeting to meet this challenge. This joint meeting will be held on January 17, 18, 19 and 20, 1943, at the Palmer House in Chicago. The keynote of this occasion will be "War Surgery" and its application to civil practice. Those members of the medical profession in good standing, who are interested in bone and joint surgery and its allied fields, may have the privilege of attending.

There will be four sections of interest connected with this program:

1. A clinical program.
2. A general scientific assembly.
3. An instructional section
   (a) Group discussion courses.
   (b) Motion pictures of surgical methods and technique.
4. Scientific exhibits.

The speakers and faculty are drawn from the leading surgical authorities of this country, as well as distinguished guests from England, Canada, South America and the Hawaiian Islands. These will include a sizable group of Army and Navy Surgeons who have had to deal directly with the war casualties from across both oceans.

Thorough, concise, short discussion courses will be offered on the following subjects. Each will have an outstanding faculty, many of whom are in military service.

I. Surgery of the Hand
II. Fractures
III. Peripheral Nerve Injuries
IV. Amputations
V. Lame Backs
VI. Surgery of the Hip
VII. Surgery of the Knee
VIII. Burns and War Plastic Procedures
IX. Foot Disabilities
X. Differential Diagnosis of Bone Pathology
XI. Reconstructive Surgery Following Trauma of the Upper Extremity
XII. Surgical Anatomy

Several special features in connection with the general program include:

A. An afternoon devoted to "Complicating Trauma Associated with Orthopedic Casualties." This will include a discussion of the following subjects:

1. "Shock—Its Early Recognition and Treatment."
2. "Blast, Crush and Compression Injuries."
3. "Thoracic Injuries."
4. "Head and Spine Injuries."
5. "Gunshot Injuries to Abdomen."
6. "Injuries to Genito-Urinary Tract."

B. One evening devoted to the subject of "Chemotherapy in the Treatment of Wounds," with eminent authorities who have studied the subject from various angles.

C. Another evening given to a debate on "The Kenny Treatment for Anterior Poliomyelitis."

There will be no time for play. Morning, afternoon and evening will be devoted entirely to the problems as they have been outlined. As has been stated previously, members of the medical profession who are interested in such a program are welcome to attend, and may receive an invitation by writing to the secretary, Dr. Myron O. Henry, 401 Medical Arts Building, Minneapolis, Minnesota. Hotel and railroad reservations should be made early.

ST. LOUIS COUNTY MEDICAL SOCIETY

Dr. Walter E. Hatch of Duluth was elected president-elect of the St. Louis County Medical Society at its annual meeting held at the Kitchi Gammi Club, Duluth, December 10. Officers who will have Society matters in charge this year are: President, Dr. Carl O. Kohlbry, Duluth; vice president, Dr. Henry E. Binet, Grand Rapids; secretary-treasurer (reëlected), Dr. R. P. Buckley, Duluth. Dr. R. J. Manley, Duluth, was elected delegate to the State Association meeting, with Dr. Robert D. Bray, Biwabik, as alternate.

Committee appointments for the year are as follows:

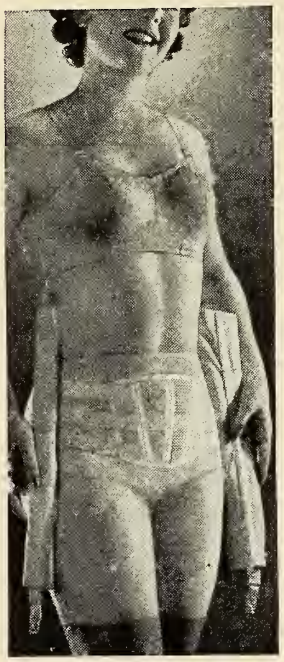
Advisory—Dr. P. G. Boman, Duluth.

Judiciary Committee—Dr. Robert D. Bray, Biwabik; Dr. D. L. Tilderquist, Duluth; Dr. E. L. Tuohy, Duluth.

Economics Committee—Dr. L. A. Barney, Duluth; Dr. F. H. Magney, Duluth; Dr. J. A. Malmstrom, Virginia.

RAMSEY COUNTY MEDICAL SOCIETY

At the annual meeting of the Ramsey County Medical Society in December, the following officers were elected to serve for the coming year: President-elect, Dr. John H. Lepak (who will take office in 1944); president, Dr. W. R. McCarthy; vice president, Dr. Justus Ohage; Dr. Joseph M. Ryan, secretary-treasurer.



RENVILLE COUNTY MEDICAL SOCIETY

At the annual meeting of the Renville County Medical Society held December 1 at Olivia, Minnesota, Dr. J. A. Cosgriff of Olivia was elected president for the coming year. Dr. A. M. Fawcett of Renville was elected vice president, and Dr. R. E. Billings of Franklin, secretary.

The meeting followed a dinner served by the Home Economics department of the Olivia high school. Twenty-eight physicians and their wives were in attendance. Dr. A. E. Sohmer of Mankato was the principal speaker.

HAVE YOU PATIENTS

With Any Of These Conditions?

Spencer Abdominal Supporting Corset shown open revealing inner support. This is a SEPARATE section, adjustable to the corset section and the patient's figure by means of flat tapes that emerge on outside of corset.

Hernia?

Enteroptosis with Symptoms?

Sacroiliac Sprain or other Back Injury?

Spinal Arthritis or Sciatica?

Postoperative Conditions?

Maternity or Postpartum Conditions?

Breast Problems?

When you prescribe a Spencer Support you are assured it will meet your specific requirements and the patient's figure needs, *because* it will be individually designed, cut and made for the one patient who is to wear it.

Every Spencer Support is individually designed for the patient of non-elastic material. Hence, the support it provides is constant, and a Spencer can be—and IS—guaranteed NEVER to lose its shape. Spencer Supports have never been made to *stretch to fit;* they have always been *designed to fit.* Why prescribe a support that soon loses its shape and becomes useless before worn out? Spencers are light, flexible, durable, easily laundered.

For service, look in telephone book under "Spencer Corsetiere" or write direct to us.

The Exclusive Collection Service in the Medical Arts Building

204-207 Medical Arts Building — BRidgeport 1151-2-3-4

Member: National Association of Medical-Dental Bureaus, an organization composed exclusively of the accredited medical-dental collection associations throughout the United States.

WASHINGTON COUNTY MEDICAL SOCIETY

Officers for 1943 were elected at the annual meeting of the Washington County Medical Society, held December 8, 1942, in the old Stillwater Clubrooms. The new officers include the following: President, Ray George Johnson, Minnesota State Prison; first vice president, Carnot H. Sherman, Stillwater; second vice president, George McCue Ruggles, Forest Lake; secretary-treasurer, E. Sydney Boleyn, Stillwater; delegate, E. Sydney Boleyn, Stillwater; alternate, Wade R. Humphrey, Stillwater; censors, J. W. Stuhr, Stillwater, E. V. Strand, Bayport, and R. J. Josewski, Stillwater.

WOMAN'S AUXILIARY

Mrs. Raymond J. Josewski, *President*
Stillwater, Minnesota
Mrs. W. H. Rucker, *Publicity Chairman*
Minneapolis, Minnesota

East Central

The East Central Auxiliary met at Cambridge December 1. Members and their husbands were dinner guests at the State Epileptic Colony. Following the dinner the ladies retired to the apartment of Mrs. D. E. McBroom where the business meeting was conducted by the president, Mrs. A. B. Roehlke. Twelve members were present.

The Auxiliary decided to keep up the state membership dues of the members of the district whose husbands are in the service.

Goodhue County

The highlights of the October meeting of the Goodhue County Medical Auxiliary included decisions to aid the Christmas Seal Sale, support the Women's Cancer Control Association, pay dues of all members whose husbands were in service and send a round-robin letter to them. Hostess for the meeting was Mrs. V. Nordholm of Ellsworth.

Hennepin County

Thirty-two members of the Hennepin County Auxiliary folded literature and placed Christmas Tuberculosis Seals in 24,250 envelopes on November 9 at the tuberculosis county headquarters. Following came the annual sale at Dayton's of handiwork of the Glen Lake tuberculosis patients, continuing for three days. Great appreciation is due Dayton's for giving the space and use of charge accounts and to Mrs. J. A. Myers, who so ably managed the sale. A sum of $1,537.75 was realized for articles sold, the entire amount going directly back to the patients.

On November 16 Mrs. James A. Johnson, president, gave a tea for wives of men in service of Base Hospital No. 26 and others. One hundred twenty-five invitations were sent, the executive board receiving guests with Mrs. Johnson.

Sarahurst is a boarding home for discharged Glen Lake patients without homes of their own to return to. Each year in December a meeting in the form of a Silver Tea for the Home's benefit is given by the Hennepin County Auxiliary. This year the $36.80 donated will be divided among the girls occupying the Auxiliary's room.

The program consisted of Christmas carols sung by the group under Mrs. Gilbert Seashore's direction and a very interesting discussion of China's educational system by Mrs. Walter Judd.

Mower County

Mrs. H. B. Allen was appointed Auxiliary Bond and Stamp Chairman of the Women's Division of the War Savings Staff at the meeting of the Auxiliary to the Mower County Medical Society in December at the home of Mrs. B. J. Cronwell, Austin.

This was the first Austin organization to give active support to the staff which plans to mobilize America's 43,000,000 women behind the war bond program. Members voted to study home nursing as a unit and the rest of the afternoon was devoted to reviewing the history of the Auxiliary.

The meeting was preceded by a dessert luncheon. The group will meet again on the fourth Monday in January at the home of Mrs. L. A. Flanagan, Austin.

Renville County

The Renville County Medical Auxiliary held its December meeting on Tuesday, the first, in the Olivia High School. The Home Economics class served a delicious dinner at 6:30 after which Dr. A. E. Sohmer of Mankato gave a short lecture on "Medical Ethics."

The women then adjourned to their meeting room for the annual Christmas Party. Mrs. J. A. Cosgriff of Olivia and Mrs. Ralph Erickson of Hector furnished the entertainment.

Rice County

Mrs. Adolph Hanson, president of Rice County Auxiliary, reports their group has organized a Surgical Dressing Unit for the Red Cross in Faribault and is conducting it with the help of outside groups. Individual members of the Auxiliary have had charge of nutrition and home nursing classes. All social activities for the year have been suspended due to the extra effort being made by all members to coöperate in every way with the war effort.

St. Louis County

At the annual rummage sale of the St. Louis County Auxiliary held November 17 in Duluth, $171.60 was realized.

Mrs. M. A. Nicholson was hostess for the November card party and guests were the wives of interns of St. Luke's and St. Mary's Hospitals.

INSURANCE ESPECIALLY DESIGNED FOR PHYSICIANS

Protection designed for physicians. Health and accident policies without frills, giving substantial protection cost only $2.00 per policy paid up in full to the middle of June, 1943.

Thirty-seven years of successful service has earned highest rating in the Insurance Digest for financial stability and loss paying record.

Communication

Duluth, Minnesota,
December 2, 1942

To the Editor:

As a member of the Saint Louis County League for Planned Parenthood, I would like to answer the communication of Theodore H. Sweetser, M.D., in your September issue, in which he criticizes the exhibit of this organization at the meeting of the Minnesota State Medical Association in Duluth, June 29, 30 and July 1. In his letter to you, he quotes at length from an article in a magazine called *America*, condemning birth control and I assume the author's ideas are substantially his.

Had Dr. Sweetser more than "noticed" this exhibit last summer, had he talked to the registered nurse in charge in order to inform himself about the Planned Parenthood clinic, he might have learned why a large number of his colleagues endorse pregnancy-spacing services, medically prescribed under circumstances of blindness, insanity, transmissable disease, subnormality and dire poverty, exhibited in the slums of New York and in the "migrant villages" now in California. He might also have learned that there is no question of "race suicide" involved, since women desiring sound contraceptive information must have at least one child, must be referred to the clinic by a doctor or by a social agency. In fact the reverse is the case, for high annual abortion figures and traffic in injurious contraceptives are a menace to human health and life. The national organization, the Planned Parenthood Federation of America, has received from physicians 35,000 requests for copies of its manual "Techniques of Conception Control."

May we suggest that Dr. Sweetser and the author of the article read recent articles in *Look* Magazine, entitled "Parenthood, U.S.A." showing what a service of medically prescribed contraceptives has done in South Carolina (where it is part of the state health program) and in other parts of the country. The negro family units of eighteen and twenty blind, diseased, rickety children pictured (before birth control) hardly represent "the daring and adventurous spirit that has made America" which the author of the quoted article says is jeopardized by birth control.

Quoting further from the article Dr. Sweetser submits, "Far from being a progressive and triumphant" movement . . . birth control is a cringing thing . . ." may I point out that a movement started a comparatively short time ago by one courageous woman against a barrage of public opposition, which has grown into a large national organization with thirty-two state organizations and 806 clinics giving baby-spacing advice to parents, with a membership of leading doctors, clergymen, sociologists, educators and economists *can* be called just that—"progressive and triumphant!"

(Mrs. Wm. H.) Genevieve J. Pryor

Note: The above has been read and approved by Dr. Elizabeth C. Bagley and Dr. W. E. Hatch, both of Duluth.

Of General Interest

Dr. Harold Hullsiek and Florence Allen, both of Saint Paul, were married December 11, 1942.

* * *

Dr. W. O. B. Nelson of the Fergus Falls Clinic has been appointed city health officer, succeeding the late Dr. W. A. Lee.

* * *

Dr. W. W. Brown of Minneapolis has moved to Grove City, Minnesota, where he will practice medicine, occupying the office suite of Dr. Julius Y. Feinstein.

* * *

Dr. B. F. Osburn of International Falls has taken over the practice of Dr. Charles E. Stafford at Beaudette, Minnesota, while Dr. Stafford is in Army service.

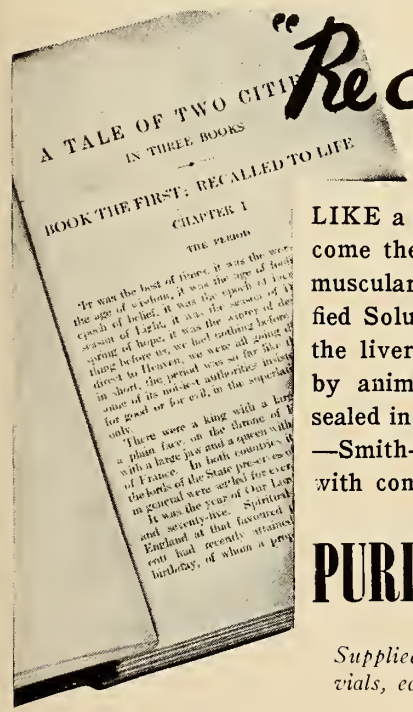
* * *

Dr. Carl J. Lund of the Estrem Clinic, Fergus Falls, has been appointed county coroner to fill the unexpired term of the late Dr. W. A. Lee.

* * *

Dr. Charlotte J. Morrison of Minneapolis has been elected county physician of Hennepin County. She is the first woman to serve in this capacity in the county. A graduate of the University of Minnesota medical school in 1934, Dr. Morrison specialized in diseases of children and later took postgraduate work in public health at Harvard University.

* * *



A mobile x-ray unit for use in anti-tuberculosis work in Saint Louis County will be purchased with the proceeds of the Christmas seal sale this year, through sponsorship of various service clubs, civic, business, farm and labor groups in the county. Part of the $15,000 required to purchase the unit was raised last year.

* * *

Dr. V. M. Baich, formerly of Saint Paul, is now a member of the staff of the Itasca Clinic at Bovey, Minnesota, taking the place of Dr. J. C. Feuling, who recently went into service in the United States Navy. Mrs. Baich, a registered nurse formerly associated with the Earl Clinic in Saint Paul, will have charge of the technical and laboratory work at the Clinic.

A Gift to Meeker County Tuberculosis Program

A new precedent in donations to public health work was created last month when Mr. J. W. Bryant of 3011 N.E. Ulysses Avenue, Minneapolis, formally presented a gift of $500 to the work of the Committee on Tuberculosis of the Minnesota State Medical Association.

The money is to be used specifically for the Meeker County tuberculosis control project of the committee and constitutes the first lay gift of this type on record anywhere for use in epidemiological work.

Behind the gift is an unusual story which was told to the committee by Mr. Bryant at the meeting. He was himself found to have an unsuspected active tuberculosis last January, he said, as a result of routine tuberculin tests and chest radiograms made of all employes of the Northern Pump Company of Minneapolis, of which he is an official. Treatment included a successful collapse of the affected lung and Mr. Bryant was back at work with a minimum loss of time. The method by which his condition was discovered and the speed and effectiveness of his treatment profoundly impressed him. His gratitude took the form of the gift to the Meeker County program because that program also aims to find unsuspected cases through routine use of the tuberculin test and x-ray on an area basis in the general population.

The gift was accepted by the committee with the approval of the Council and will be used, it was announced, in accordance with the wishes of the donor, to help finance the county-wide tuberculosis survey of Meeker County. The program of the committee is modelled in essentials upon the program of the veterinarians for the control of tuberculosis among cattle. The demonstration in Meeker County is coupled with an accreditation plan by which any county measuring up to standards set by the committee may be accredited by joint action of the Minnesota State Medical Association and the Minnesota Department of Health.

"I realize," Mr. Bryant told committee members, "that the problem of arresting tuberculosis in the individual is a minor one in comparison with the larger problem of controlling it in the general population. I have no words to express my admiration for you and the Meeker County doctors in your attempt to create a working model here for the control of tuberculosis."

Mr. Bryant was made an honorary member of the committee at this meeting.

Physicians in Service

Dr. Stuart Lane Arey of Excelsior, Minnesota, reported for duty at Quantico, Virginia, in December as a lieutenant in the United States Navy.

Dr. Philip Rains Beckjord of Willmar, now serving with the United States Army, has been promoted to the rank of Major in the Medical Corps. He is at present holding the position of Executive Officer in a Medical Battalion at Camp Van Dorn, Mississippi.

Dr. N. O. Monserud, a member of the Raiter Hospital staff at Cloquet, Minnesota, is in training at San Antonio, Texas, having received his commission as first lieutenant in the United States Army in November.

Dr. George Olds of Waseca, a captain in the Air Corps, is stationed at George Wright Field, Spokane, Washington. Dr. Olds has been assigned to an engineers battalion and is preparing for foreign service.

Commander Irwin Norman, University of Minnesota graduate in the class of 1928, has joined the staff of General Douglas MacArthur's command as fleet surgeon of the Southwest Pacific fleet. In that position he will be in charge of all medical activities in the area for the United States Navy. In taking his new post in the Southwest Pacific Commander Norman will complete service which will have taken him almost around the world. It will be recalled that he was a member of the Harriman-Beaverbrook mission to Moscow and Kuibeyshev, Russia, last year. Commander Norman visited his parents, Mr. and Mrs. August Norman, at Willmar, en route to his new post.

be in charge of the obstetrical ward, and by the regular staff of nurses and assistants. Miss Wolfe received her nurses' training at Hillcrest Hospital, Minneapolis, and was affiliated with the Minneapolis General Hospital and the Covell and Community Hospitals in St. Peter as a nurse before her appointment by the hospital board.

* * *

A general letter has been sent by the State Board of Control to superintendents of all state institutions asking that poisonous drugs and similar substances be confined strictly to drug storerooms and kept separate from any items of food. This is being done as a precaution in averting any such tragedy as occurred recently in a state hospital at Salem, Oregon, with the death of forty-seven inmates, whose food had been contaminated with roach powder.

The Elizabeth Kenny Institute, occupying the building at Eighteenth Street and Chicago Avenue, Minneapolis, was formally dedicated with appropriate ceremonies, Thursday, December 17. A dinner in Sister Kenny's honor was given after the ceremonies at the Nicollet Hotel.

Treatment of constipation by mechanical means may prove effective

If habit-forming laxatives and cathartics have proved inadequate or are not tolerated, sometimes mechanical means will restore normal bowel tone. As an adjunctive treatment these dilators have proved of value also in the therapy of hemorrhoids by elimination of constipation, relieving congestion of blood and establishment of vigorous circulation. Not advertised or sold direct to the laity. Write for brochure.

Biolac provides for all nutritional needs of the young infant except vitamin C. You save valuable time because there are no extra formula ingredients to be calculated.

Biolac assures formula safety

Since mothers simply dilute Biolac with boiled water as you prescribe, there is less chance of upsets arising from errors or contamination in preparing formulas.

NO LACK IN BIOLAC

Borden's complete infant formula

• *Biolac is prepared from whole milk, skim milk, lactose, Vitamin B_1, concentrate of Vitamins A and D from cod liver oil, and ferric citrate. It is evaporated, homogenized, and* sterilized. *For professional information, write Borden's Prescription Products Division, 350 Madison Avenue, New York City.*

PRIVINE* HYDROCHLORIDE

New Powerful Synthetic Vasoconstrictor

▶ ***PRIVINE-Hydrochloride*** acts quickly to clear nasal congestion due to Colds, Hay Fever, Rhinitis, Ethmoiditis, and Rhinosinusitis. Its markedly prolonged duration of effect is outstanding . . . in most cases the vasoconstriction lasts from 2 to 6 hours.

▶ Great care has been exercised in preparing ***PRIVINE-Hydrochloride*** solutions to meet all requirements for modern nasal medication[1]. The isotonic and buffered solution restores the normal pH of the nasal mucosa and maintains ciliary activity.

▶ ***PRIVINE-Hydrochloride*** (Brand of Naphazoline) applied either by drops or nasal spray is preferred by physician and patient due to its lack of local or systemic side effects. Available in 0.1% solution in 1 oz. bottles and also 0.05% in 1 oz. bottles for children. Literature and samples on request.

For timely and effective control of Scarlet Fever...

Treatment . . .

Scarlet Fever Streptococcus Antitoxin

GLOBULIN *Lederle* MODIFIED

Prevention . . .

Scarlet Fever Streptococcus Toxin

Lederle

TODAY ANTITOXIN THERAPY may be administered with comparative safety —for both mild and severe scarlet fever. The advanced process of serum refinement by Parfentjev of Lederle Research Laboratories has greatly reduced the incidence of serum sickness[1]. This Globulin-Modified antitoxin usually brings about a sharp drop in temperature and prompt disappearance of symptoms[2,3]. Early administration is advised to thwart the development of complications[4].

In infected, susceptible persons, "Scarlet Fever Streptococcus Antitoxin *Lederle*" may be injected for prophylaxis, and a passive immunity is produced, lasting about two weeks. However, this temporary measure must be followed one week later by active immunization for lasting protection.

Sterility Test

"Scarlet Fever Toxin *Lederle*," for active immunization, is a highly potent and carefully standardized preparation. Complete immunization can be achieved only if a full course of undivided doses is given. By such a method 90-95% of individuals may be rendered Dick-negative, the majority remaining so for as long as 12 years[4].

Some recommend that every child be given a Dick test on entrance to school or an institution, and that a record be kept of the result[5]. Dick-testing and immunization of susceptible individuals is indicated[6] in emergencies such as threat of an epidemic. It is a timely procedure for the large numbers of children who are being moved, in many parts of the country, into over-crowded war-plant areas.

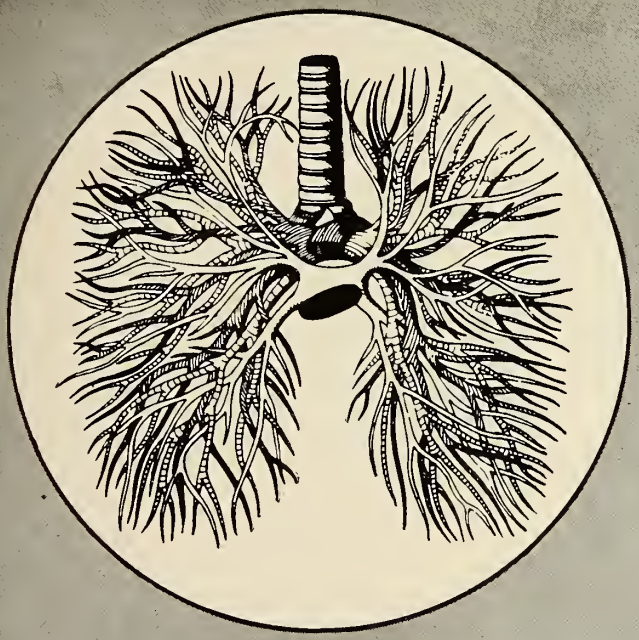
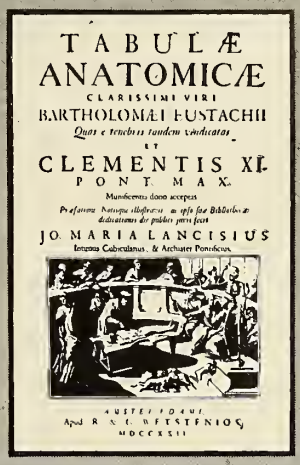
THOUSANDS OF BACTERIOLOGICAL TESTS MAKE DEXTRI-MALTOSE SAFE





Skilled bacteriologists constantly test Dextri-Maltose

THOUSANDS of samples of Dextri-Maltose, secured both during the course of manufacture and after packing, are continually analyzed bacteriologically. This close correlation between laboratory and factory results in a product having a remarkably low bacterial count—well under 100 per gram. A quarter of a century of clinical success has demonstrated that such ceaseless vigilance is indispensable to safety. Here, where the life and health of the infant and the reputation of the physician are in the balance,—VALUE, NOT PRICE, IS THE TRUE MEASURE OF ECONOMY.

FOR SALE BY SURGICAL DEALERS AND DRUGGISTS

To THE PATIENT who is ill or care-obsessed the administration of Ipral may mean the difference between long, dragging hours of wakefulness and a sound, restful sleep closely resembling the normal.

Used for more than fifteen years as a safe, effective sedative, Ipral, an intermediate acting barbiturate, produces a 6- to 8-hour sleep from which the patient awakens generally calm and refreshed. Dosage is small . . . absorption and elimination rapid . . . and cumulative effects avoidable by proper dosage regulation.

HOW SUPPLIED

Ipral Calcium (calcium ethylisopropylbarbiturate) in 2-grain tablets and in powder form for use as a sedative and hypnotic. ¾-grain tablets for mild sedative effect throughout the day.

Ipral Sodium (sodium ethylisopropylbarbiturate) in 4-grain tablets for pre-anesthetic medication.

Elixir Ipral Sodium in pint bottles.

TUBERCULOSIS OF THE EYE

F. H. HAESSLER, M.D.
Milwaukee, Wisconsin

HOWEVER alluring the many theoretical problems are, for the practicing oculist, the central problems of tuberculosis are diagnosis and therapy. The two functions expected of a physician are that he give his patient reliable advice and, where possible, institute such measures as will beneficially influence the course of the disease. In tuberculosis it is of particular importance that the fundamental reactions be understood because an etiological diagnosis is of importance. It is on the basis of such diagnosis that *specific therapy* can be instituted.

The diagnosis of tuberculosis of an eye is never completely certain. It is always a diagnosis of probability, and it must be admitted that the prejudices of the individual diagnostician play a part in the decision. This makes it impossible to arrange reliable statistics as to the occurrence of tuberculosis of the eye. Some German clinics classify over one-half of their cases of uveitis as tuberculosis, while some American workers whose attention is centered on focal infections find no more than 5 per cent. The diagnosis is based on four kinds of data, namely:

1. An understanding of the reactions and the change of reaction in tissue in general produced by tuberculous infections.
2. The characteristics of eye lesions which previous clinical and pathological experiences have shown to be tuberculous.
3. Evidence that the patient has been infected with tuberculosis as is shown by reactions to the injections of tuberculin and by the presence of tuberculosis in other organs.
4. The inability to demonstrate another etiology.

When tubercle bacilli first invade a body, they cause an inflammatory reaction or tubercle formation at the site of invasion and are also disseminated to the regional lymph-nodes. In most cases the portal of entry is the lung, and the primary complex involves pulmonary tissue and the tracheobronchial lymph-nodes. Other organs may also be the seat of primary infection: for example, the intestine or the conjunctiva. The latter is rare but is occasionally seen as a unilateral ulcerated conjunctival nodule with swelling of the preauricular lymph-node almost always in young patients. The primary reaction is probably stimulated by the lipoid fraction of the tubercle bacillus body. Wherever introduced into a hitherto uninfected body, the tissue reacts either with inflammation or tubercle formation. It is the relative number of bacilli and the site of their lodgment that determines which of these reactions takes place.

From this primary complex, tubercle bacilli may be transferred to other parts of the body. In most instances the secondary infection is spread by way of the blood. This is true even of the choroidal lesions accompanying tuberculous meningitis. Much more rarely is the infection spread by the lymphatics or by direct extension from contiguous structures. The nature of the secondary lesion depends not only on the site

Presented before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

of the metastatic lesion but on the reaction of this tissue. The reaction of the secondarily invaded tissues differs from that at the site of the primary complex because the changes take place in the tissues of the host in the weeks that follow primary invasion by tubercle bacilli. The tissues become hypersensitive or allergic and an immunity develops which is a mechanism consisting of several factors not completely understood which bring about increased resistance to the bacillus.

The allergy is a characteristic reaction of the human body to all foreign protein of whatever nature. As a result of primary infection, the tissues of the host become allergic to the tubercle bacillus protein. This tuberculo-protein or antigen combines with the allergic antibody which is produced in the tissue cells—not the body fluids—to form a necrotizing poison. Everything that happens at the site of an uncomplicated allergic reaction is merely the standard reaction of the body to a chemical irritant. With properly adjusted concentrations, it would be possible to produce with sulphuric acid a lesion indistinguishable histologically from antigen antibody inflammations. It causes cellular damage and may seriously impair healing. It is also largely responsible for the inflammatory reaction which is largely a vascular reaction. Allergy does not, however, induce tubercle formation. That is a response to the lipoid of the bacillus. Tubercle formation requires no inflammatory paralysis of vascular walls for its evolution. It is the most primitive organized reaction to an invading organism and can occur in animals that have no vascular system. Tubercles can form independently of blood vessels in any tissue to which mononuclear phagocytes have access—even in vitro in tissue cultures.

The other change produced by primary invasion of the host is immunity. That is a complex reaction which consists of a number of factors which tend to fix the bacilli near the site of invasion, to limit their spread, and to inhibit their growth so that repair may take place in the tissue of the host. The repair may result in complete destruction of the invader, and restitution of the invaved tissue to its normal state or more often an encapsulation of an infected area by a thick fibrous coating which protects surrounding tissues from invasion.

The two mechanisms, allergy and immunity, are separate entities, and allergy plays no part in immunity. It is doubtful that allergy even helps fix the bacilli at the site of invasion. This is accomplished by a specific precipitin-like mechanism which is part of the immunity reaction. When allergic inflammation occurs about a quiescent focus, there is a marked tendency to spread rather than to immobilization. The allergic reaction may also destroy newly-formed granulation tissue and so hinder rather than help the healing process.

Allergy seems unrelated to immunity. It can easily be produced as a response to the injection of dead tubercle bacilli or tubercle bacillus protein alone while immunity develops only as a response to the introduction of living tubercle bacilli. In the course of time the allergy wanes, and after the lapse of months following the injection of antigen, disappears. Despite the absence of allergy, however, such animals are found to be highly immune. In animal experiments, the criteria of allergy are reactions to injections of antigen: immunity is judged by survival time of the animal.

Allergy and immunity are the two important factors which determine the nature of all secondary or metastatic tuberculous lesions. Each may vary in quantity. A high degree of allergy or hypersensitivity makes a lesion highly inflamed and exudative, breaks down new-formed granulation tissue and hinders healing. Immunity inhibits the growth of tubercle bacilli, and prevents their spread, and allows reparative processes to proceed.

A host with high allergy and low immunity has the most malignant form of progressive inflammatory destructive and exudative tuberculosis. It is the type most dangerous to treat with tuberculin. On the other hand, low allergy and high immunity produces benign, torpid, productive fibrotic lesions with a tendency to heal. All possible quantitative combinations of these two factors may occur and produce the innumerable clinical manifestations of tuberculosis. There are, of course, other factors, some probably unknown and others well known, such as the number and virulence of the infecting bacilli.

In the young, when metastases occur soon after primary infection and before the host has become highly allergic, one often finds discrete tubercles with little inflammatory reaction. The less marked the inflammatory aspect of the le-

sion, the better the prognosis. In somewhat older patients who have become highly allergic, the lesions are characterized by severe inflammation and copious plastic exudation. The whole posterior surface of the cornea may become covered with mutton-fat deposits. The tuberculosis, usually uveitis, which begins later in life, say after forty, is usually free from marked congestion. The patients come for slowly progressive failing of vision, not redness or pain in the eye and strikingly the great majority are women.

Type of Lesion

Any structure of the eye may become the seat of a tuberculous lesion, but in the overwhelming majority of cases it is the uvea. This preponderance is so great that all other tuberculous lesions of the eye seem rareties. Tuberculosis has a special prediliction for vascular and connective tissue, hence the uvea is the tissue first involved. From here it may spread to other tissues of the eye.

The conjunctiva may be the seat of a primary form of exogenous infection. This is a unilateral ulcerous nodule accompanied by swelling of the preauricular gland.

Secondary conjunctival tuberculosis may take the form of a proliferative lesion of granulation tissue which may ulcerate or not, and occasionally becomes manifest as a tumor-like tuberculoma. In contrast to other forms of episcleritis, such tubercles are indolent. They do not ulcerate, and if they heal at all, do so without loss of substance. Differentiation from other nodular lesions such as aphthalmia nodosa, vernal catarrh, and others is not always possible and biopsy is advisable.

The corneal lesions are probably always extensions from a metastatic uveal lesion. Sometimes extension is direct and sometimes by rupture of a tubercle into the anterior chamber or Schlemm's canal. The clinical picture is not pathognomic. Suggestive is the marginal distribution and anterior position of the infiltrated areas. They tend to heal and to recur. A deep central infiltrate is sometimes observed and is believed to result from aqueous infection. Direct extension from the sclera produces sclerosing keratitis.

Deep scleritis is characteristically tuberculous. It is extremely resistant to treatment, protracted in course, and is apt to recur. The weakened sclera may bulge. Histological preparations are characterized by typical tubercle formations.

Uveal tuberculosis is so much the most common manifestation of the disease that ocular tuberculosis means uveitis to many. When actual tubercles are visible or the equally characteristic evanescent semi-transparent Koeppe nodules on the pupillary margin, the diagnosis does not present much difficulty. When the iritis is diffuse, an etiological diagnosis is less obvious, often difficult and frequently impossible. When the exudate is serous and is characterized by cells or cell clumps in the aqueous and well-formed cell masses floating in the convection current in the aqueous or deposited on the post corneal surface, most characteristically in the lower quadrant, a diagnosis of tuberculosis, syphilis, or sympathetic ophthalmia suggests itself. Absence of preceding trauma and a negative Wassermann reaction make tuberculosis a likely diagnosis. When the exudate is fibrinous, the aqueous is also characterized by freely floating cells, but they soon become entangled in a fibrinous network and all orderly movements stop. Efflorescences on the pupillary margin are never seen in this type. The stroma becomes swollen, hyperemic, and hemorrhagic and eventually hypopyon and hyphema develop. This is the picture associated with acute iritis whose etiology seems most often to be focal infection or gonorrhea.

Unfortunately these clinical pictures are only suggestive of certain etiological factors and by no means pathognomic. It must be emphasized that the eye may respond to the stimuli produced by tuberculous infection in a multitude of ways and even the most stormy course does not rule out tuberculosis.

Before the observation of von Michel it was thought that only those ocular inflammations associated with visible nodules could be called tuberculous. He recognized the fact that an iris which was clinically free from nodules might still show typical miliary tubercles histologically. In this country Verhoeff reported a case of iritis whose chief characteristic was acute fibrinous exudate without any nodules. Tuberculosis was not even suspected until typical tubercles were seen in the histological preparations made from the eye after it was enucleated for pain. He has collected several similar instances and other observers have corroborated these findings.

Similar observations can be made in the choroid. The nodular lesion immediately sug-

gests a tuberculous etiology, while in the case of diffuse and exudative lesions, this etiology is less readily suspected.

In the retina the characteristic tuberculous lesion is the syndrome known as recurrent juvenile vitreous hemorrhage. If the hemorrhage is small so that the fundus is visible, one frequently sees localized opacities associated with the retinal veins which are the clinical expression of tubercles in the venous wall. This has until recently been considered a disease sui generis. It has been rather generally believed to be a manifestation of tuberculosis although even this has been doubted by Marchesani who believes many cases of retinal perphlebitis to be part of generalized endarteritis. The recent work of Meyer, however, based on histological study of an unusually large number of eyes makes it clear that the disease is in most instances tuberculous. Furthermore, he demonstrated that it is not usually an isolated disease but in the majority of cases an extension of an uveitis which had not been clinically manifest. Most often the uveitis precedes the perphlebitis but the opposite may be true. There is no essential difference between the isolated perphlebitis and one consecutive to iridocyclitis. Clinically the only difference is that the former is more often associated with hemorrhage. Ophthalmoscopically the pictures are identical when not obscured by hemorrhage.

The substratum of the clinical mantle about the veins is an infiltration of the perivascular lymph sheath with lymphocytes. The infiltration consists for the most part of round cells only very occasionally of specifically tuberculous granulation tissue. The process is often accompanied by proliferation of the cells of the vascular wall so that the lumen is obliterated, which is followed by the formation of new vessels which become clinically visible. Many transitions are found between these infiltrates and tubercle in the nervous tissue.

The tuberculosis is partly transmitted from the anterior uvea by means of the lymphatic circulation in the perivascular lymph sheaths which surround the blood vessels of the retina which have no other lymphatics. Infection has also been observed to arise by direct perforation of a choroidal tubercle which may be followed by numerous superficial tubercles on the inner surface of the retina from dissemination on the vitreous. Direct hematogenous infection of the retina is also possible.

Relation of Ocular Tuberculosis to Tuberculosis Elsewhere

Since ocular tuberculosis is a secondary infection, there are two points on which a general examination can give diagnostic aid. It can sometimes find the seat of the primary lesion and even uncover evidence that it is active in giving off bacilli. When this is not possible, a positive intradermal tuberculin reaction can at least demonstrate that the patient has in his body living or recently dead tubercle bacilli that are responsible for his sensitivity to tuberculo-protein. In absence of this, an etiological diagnosis of tuberculosis has little support.

The consensus of opinion among ocular tuberculographers is that it is probable that the primary lesion for most ocular tuberculosis is intrathoracic, specifically hilus gland tuberculosis. Physical examination and refined roentgenograms give very reliable information about these lesions. Since the bacilli are frequently disseminated from a lymph-node breaking through into a vein, they must pass through the pulmonary circulation before they again have access to the general circulation. One would expect to find metastatic lesions in the lung as well as in the eye in at least some of the patients. This has indeed been found to be true. Werdenberg has demonstrated roentgenograms which give evidence of miliary tubercles in the eye corresponding in age with the ocular lesion. In a study of 500 patients, Werdenberg found that roughly 60 per cent had mild intrathoracic tuberculosis associated with severe ocular tuberculosis; in 30 per cent the two lesions were equally seen, and in 10 per cent there was an inverse relationship; namely, the pulmonary disease was severe and the ocular lesion mild.

These findings must not be believed to be in disharmony with the statement based on experiences of many tuberculographers with thousands of patients, namely, that ocular metastasis is the greatest rarety in patients with severe progressive pulmonary disease. This progressive pulmonary disease is probably the result of exogenous reinfection. Patients whose immunity is kept at a high level by the escape into his bloodstream of a small number of bacilli from a lymph-node from time to time is able to cope

with the reinfection. The patient with ocular metastasis is in this position.

The tuberculin reaction is a test of allergy or hypersensitivity. Since allergy wanes in the course of months unless it is kept at its level by the introduction of new tuberculo-protein from bacilli in a lymph-node or other site of inflammation, a positive reaction is good evidence that the patient harbors tubercle bacilli. This tuberculosis may be inactive in an encapsulated lesion which is not a source of metastasis. If the test is negative it may mean that the patient has never been infected with tuberculosis, or long enough before the test so that allergy has waned, or so recently that allergy has not yet developed. This takes several weeks (four to eight) to occur. The test may also become negative in moribundi, febrile patients and after therapy with tuberculin.

In performing the tuberculin test, Koch's old tuberculin (O.T.) in dilution is commonly injected intradermally so that 1/1000 milligram O.T. is introduced into the skin. If this fails to cause hyperemia and edema, 1/100 milligram is injected and finally 1/10. One-tenth cubic centimeter of dilution, 1/100,000, 1/10,000, and 1/1000 respectively contain this amount of O.T. more recently the American Tuberculosis Association has been recommending a product known as p.p.d. These letters are the initial letters of "purified protein derivative." It represents the protein extracted from cultures of strains of tubercle bacilli whose virulence and behavior are well known and purified by means of a standardized chemical procedure. Its great advantage is absolute uniformity of the re-agent and, therefore, the production of comparable results for statistical analysis. The product is dispensed in tablets in which p.p.d. is incorporated in sterile lactose tablets in quantities of 0.0002 milligrams and 0.05 milligrams. The smallest dose detects a high percentage of total positive reactions with a minimum of severe reactions. The larger dose is designed for repeat tests on those whose reaction was negative with the smaller dose. The first dose is equivalent to one or two 1/1000 milligrams O.T., the second to 1 milligram O.T. The skin reaction has been classified:

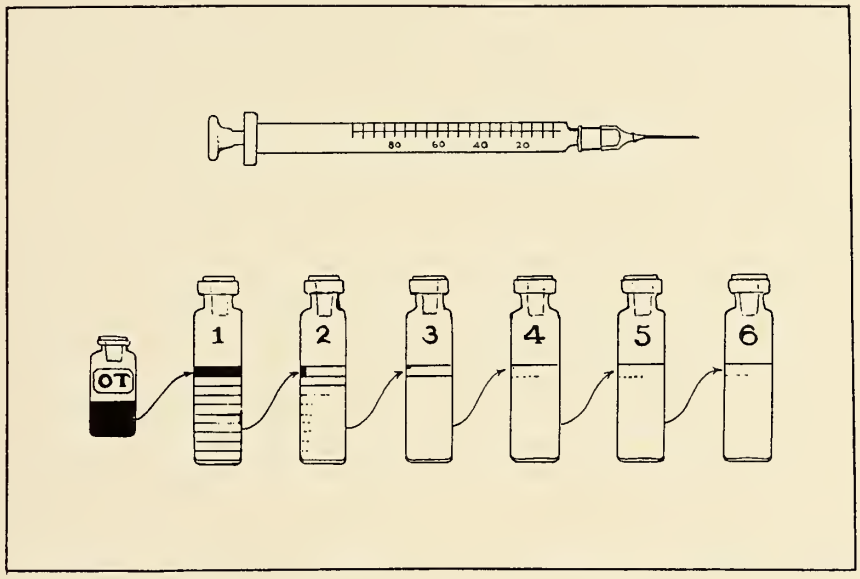

Diagram showing the entire equipment needed for therapy with tuberculin. One-tenth c.c. O.T. is taken from the purchased vial with a tuberculin syringe without removing its rubber stopper. This 1/10 c.c. O.T. is injected into another vial, through its rubber stopper containing 9/10 c.c. physiological salt solution. One-tenth c.c. of dilution No. 1 is injected into the next vial of the series to make dilution No. 2 (1/100 O.T.). The process is repeated serially.

+	some redness and edema between 5 and 10 millimeters in diameter
++	redness and edema between 10 and 20 millimeters in diameter
+++	redness and edema greater than 20 millimeters in diameter
+++++	marked redness and edema and some necrosis.

When testing a patient who has an eye lesion that suggests high allergy or is in so vulnerable a tissue as the retina, it is wise to be more cautious in using the diagnostic tests and injecting only 1/100 cubic centimeter of the 1/100,000 dilution O.T. or the smaller dose of p.p.d. or even less than this. If negative, the test can be repeated with a larger dose.

Both the finding of the intrathoracic lesion of active tuberculosis and a positive tuberculin reaction do not prove that the eye lesion in question is tuberculous. They make such a diagnosis possible. When the eye lesion has characteristics which suggest tuberculosis, the diagnosis is still more probable.

A fourth point in the etiological diagnosis is the exclusion of other possible etiological factors if all factors other than tuberculosis can be excluded, the diagnosis becomes still more probable. It can only be made certain after the eye has been enucleated.

Among lesions which may most nearly simulate tuberculosis are syphilis and sympathetic ophthalmia. The latter need not be considered in the absence of antecedant trauma. A negative Wassermann excludes syphilis except in cases of interstitial keratitis and here other stigmata of congenital syphilis are diagnostic.

Non-tuberculous foci of infection form a large group of possible primary lesions. It is as difficult to establish their participation in the geneses of a secondary ocular infection as that of tuberculosis itself.

The most likely seat of a nontuberculous infection which may involve the eye is the prostate gland. Teeth and tonsils and other organs may also be suspected and if disease is found in them, proper treatment should be applied.

Treatment

The treatment of patients with tuberculosis of the eye should be managed with the coöperation of an internist. The patient is ill with tuberculosis, and the fact that the seat of the inflammation is the eye and not the lung makes it no less important to apply such general measures as diet, rest, heliotherapy, and other forms of stimulaton as will increase his resistance to tuberculosis Indeed, some patients with ocular tuberculosis do not improve until these general measures are applied. Others get well with no other treatment than just such general measures. E. V. L. Brown reported his experience with four such patients. Many of the patients with ocular tuberculosis do indeed have an intrathoracic lesion as well which makes the internist's advice essential.

Such general measures as are used in the treatment of any other inflammatory disease of the eye are also indicated in tuberculosis—hot compresses, atropin, and nonspecific protein therapy. When all else fails, gold salts and roentgenotherapy are advised.

Most important to discuss, however, is the question of specific therapy with tuberculin. If one does not believe in its efficacy, there is hardly a logical reason for differentiating tuberculosis from the many other etiological factors which cause inflammation in the eye.

It must be emphasized that tuberculin can be harmful and extremely dangerous if it is improperly used. To use tuberculin intelligently, one must bear in mind its mode of action and the rationale of its application.

Tuberculin therapy may be used on the basis of one or both of two hypotheses.

1. It may desensitize the individual.
2. It may increase his local immunity about the focus of tuberculosis in the eye.

The process of desensitization is brought about by repeated injections of small doses of tuberculin, so small that one never produces a local or general reaction of any kind. The purpose of this mode of application is to reduce the patient's allergy to tuberculo-protein. In highly allergic patients, the reaction between antigen liberated at the site of the lesion and the antibodies produced by the defensive mechanism produces a necrotizing agent which destroys the newformed granulation tissue in the lesion and thus prevents its healing.

As long as one succeeds in administering doses that are sufficiently small, it is not harmful. Of course, it is possible because of error in judgment to give a dose that is too large for the patient at the time and do harm.

When treating on the hypothesis that tuberculin therapy increases immunity, one also gives repeated doses but strives for at least a local reaction. I doubt that anyone still advocates doses that produce a focal reaction. A focal

reaction would be highly dangerous in proliferative lesions and certainly destructive in exudative lesions in highly allergic eyes.

It is probable that the desensitization program is the more effective. In the practical routine of tuberculin therapy, the oculist guides himself by the appearance of the eye as therapy progresses, but he must never forget that the patient may have other tuberculous lesions—in particular intrathoracic lesions—and that he must have the coöperation of an internist to watch the other organs.

Choice of Tuberculin

It possibly makes little difference which form of tuberculin is used, although many experienced workers have decided preferences. If desensitization to tuberculo-protein is the basis of therapy, it certainly can make no difference, and p.p.d. would be the product of choice because of its chemical uniformity. However, since we are still inadequately informed, we cannot arbitrarily disregard personal opinion and belief based on clinical experience. Although we intend by our injection to desensitize the allergic patient, we may at the same time be increasing immunity factors when we use such whole products as Bacillary Emulsion (B.E.). This is not true of p.p.d. Theoretically, the only objection to B. E. is that we may because of inadequate division of particulate matter inadvertently introduce a much larger dose of protein with an occasional injection. This could not be true of O.T.

The factor of real importance, however, is the dose. One should start with extremely small quantities. It is convenient to make a series of dilutions, 1/10, 1/100, and 1/1000 and so on and number them to correspond to the number of zeros in the denominator than as dilution 1, 2, 3, and so on. Injections are best made intradermally.

It is wise to start with 0.01 cubic centimeter of dilution 6, never stronger than 5. In retinal lesions or in exudative lesions of the anterior chamber, or any lesion which we believe to be dangerous because of its location or the allergic state of the eye, we use No. 6.

We inject twice weekly and make each dose twice as large as the preceding one. As the doses get larger, the intervals may be increased to as much as one week. If we have reason to suspect that the lesion is a dangerous one, the dose may be increased by only one-half the preceding dose. It is dangerous, however, to schematize. One must carefully watch the eye for the slightest sign of reaction. In all cases of doubt, it is wise to give a smaller rather than the larger dose and to increase slowly.

References

In treating a subject briefly, there is always great danger that one presents data and their interpretation too schematically. The following references are given so that more extensive reading will dispel any false notions to which my condensation may give rise.

MODERN METHODS OF CONTROL FOR MEASLES, SCARLET FEVER, AND DIPHTHERIA

ARCHIBALD L. HOYNE, M.D.
Professor of Pediatrics, University of Illinois College of Medicine
Chicago, Illinois

Measles

OF ALL the diseases known to mankind there is none more likely to occur in a lifetime than measles. This very fact is evidence of our inability to control the infection. From antiquity to the present day there seems to have been little change in the widespread distribution of measles and the universal susceptibility for all races without regard to climate, habits or social status. Age only is a restraining factor for we know that measles seldom occurs during the first three months

Presented before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1942.

of life. But advancing years exert no check on susceptibility. Panum's vivid account of what happened in the Faroe Islands in 1846 is a good illustration that grandparents and grandchildren may share alike in respect to this disease. There it may be recalled that 6,000 of the 8,000 inhabitants were attacked by measles.

Epidemics of measles come with increases in population. When the supply of susceptibles has been exhausted there must be a pause until more children are born and others have advanced to the age of distinction when they may have measles. London has had an epidemic of measles every two years since 1856 until fateful 1940, when the bombing of the city seemed to have blasted the infection from the atmosphere. For although an epidemic was due none developed. In Chicago we had our greatest epidemic in 1938 when there were 37,831 cases. The next outbreak came last year, so there have been in 1942 only a few sporadic cases during March and April, months when the disease is at its peak in years of prevalence.

Because adults are not immune to measles unless they have experienced an attack, this infection is often of major importance in time of war. Among American troops from 1917 to 1919 there were 98,000 cases of measles. But it was not the office boys, not the city dwellers who suffered; it was the strong, husky youths from the small towns and country districts who had never had measles because they escaped exposure when children.

Measles is generally regarded as a virus disease, although some years ago Tunnicliff reported a green producing diplococcus as the causative factor. Virus diseases are usually more difficult to control than bacterial diseases because of the problems concerned in developing protective vaccines. Moreover, measles is a respiratory disease; it may not only be transmitted before the eruption but it is more contagious in the catarrhal stage than at any other time, and it is one of the most contagious of all diseases. On the other hand, the contagion of measles is not tenacious and it is short-lived. So the chances of measles being conveyed to a susceptible is far greater before the eruption has appeared than afterward. Some believe that by the time the eruption is fully developed the danger of contagion has practically ended.

The foregoing comments are presented for the purpose of emphasizing the perplexities that accompany any efforts to control measles. But this does not mean that no attempts should be made to prevent measles nor that successful procedures do not exist to accomplish that aim within certain limitations.

Immunization.—There is no artificial method for establishing a permanent protection from measles. And until some means is developed for active immunization satisfactory control of the disease cannot be accomplished. Rake and Shaffer have reported a new measles vaccine but little is yet known concerning its value. Temporary protection from measles is possible by the intramuscular injection of convalescent measles serum. Usually 7.5 c.c. of convalescent serum when given within three days of exposure will prevent the disease. The immunity, however, is not likely to endure for more than two or three weeks. Therefore, if a second exposure occurs two weeks or more after the administration of serum, a second injection will be required for further protection. Because human serum is used there should be no fear of reaction. If human convalescent serum is not available, whole blood from a parent who has a reliable history of having had measles may be substituted. But under the latter condition the quantity injected must be much greater, generally at least 30 c.c. being required.

Placental extract is also used for passive immunity and has the advantage of being easily available, as a rule. When the purpose is to prevent the disease some advise that 2 c.c. of this placental extract be injected intramuscularly at time of exposure and that 2 c.c. more be given about one week later.

Modification.—If any one of the measures just described is instituted more than three days after exposure, the susceptible person will probably develop measles in an attenuated form. Sometimes this result is preferable to prevention because a modified attack of measles leads to permanent immunity as a rule; whereas, absolute prevention is only a temporary state of immunity.

In an epidemic year or at any time that measles is known to be present in a community, chil-

dren with colds, no matter how slight, should be excluded from school and kept at home. Children who have had measles and live on the premises when an active case of the disease exists are allowed to attend school for two reasons: (1) it is assumed that second attacks of measles do not occur and (2) the infection is not carried by a contact for any considerable distance.

Placarding the premises where a case of measles exists is of no practical value in controlling an epidemic.

Scarlet Fever

Although scarlet fever is more subject to control than measles, it continues to be a major public health problem. Epidemics do not occur in any fixed cycles of regularity but the level of incidence remains on a relatively high plane with only slight recessions from year to year in ordinary times. During the epidemic of influenza in 1918, scarlet fever was at a low ebb in Chicago. However, the disease was unusually prevalent in 1916–17. In the present year, scarlet fever has continued the downward trend that became evident in 1941. It is interesting to note in this connection the experience of London in 1939 and 1940. Notwithstanding the exodus of hundreds of thousands of children from the cities in the fall of the former year to escape possible bombings and the return of more than 80 per cent by the close of the same year, there were fewer contagious diseases in London during 1940 than in 1939. No explanation is offered for this occurrence.

Efforts have been made to control scarlet fever by means of hospitalization. In small communities this plan should afford a fair degree of success but in larger cities it is a failure. Likewise quarantine measures applied to homes have often been unsatisfactory for the purpose of control. The explanation for this situation is not difficult. Among the scarlet fever patients entering contagious disease hospitals comparatively few give a history of contact with a known case of scarlet fever. How do they acquire the infection? Our answer must be that patients with tonsilitis or acute pharyngitis are not isolated, nor are those with streptococcic sore throats. Yet these conditions are all contagious and may be due to organisms capable of producing scarlet fever. Moreover, there are arbitrary periods established for quarantining scarlet fever patients. If the time is three weeks we regard the patient as contagious on the twentieth day of the disease but not on the twenty-first. This means that about 60 per cent of scarlet fever patients are turned loose on the public as scarlet fever carriers. Of course, the ideal procedure would be to require negative cultures for hemolytic streptococci from the nose and throat before isolation is terminated. But in large cities such a plan is not feasible.

Active immunization against scarlet fever by artificial means is the accomplishment most desired. Whether this ideal can now be achieved must depend upon one's conception of this disease. There is no doubt that a positive Dick test can nearly always be changed to negative by injections of scarlet fever toxin according to the Dick method. Nevertheless, the Dick negative individual is not immune to infection by hemolytic streptococci from a scarlet fever patient. But should this occur no rash is likely to appear on the skin even though the throat presents the characteristics of scarlet fever. Moreover, fever and adenopathy may be accompanying symptoms. Under such circumstances a diagnosis of scarlet fever is not likely. But if scarlet fever can occur without a rash, as is generally admitted, how are we to know that the condition is not scarlet fever? Possibly injections of scarlet fever toxin immunize only against the toxemia of scarlet fever, including the rash. Even if we grant only that, the procedure seems advisable. Moreover, if the five regular subcutaneous doses are feared because of possible reactions, the toxin may be administered in three intracutaneous doses of 0.1 c.c. each. The amount to be injected may be determined as follows: 1st dose, 0.2 of third regular dose; 2nd, 0.15 of fourth regular dose; and 3rd, 0.1 of fifth regular dose—all given at weekly intervals.

For passive immunization, convalescent scarlet fever serum in 10 c.c. doses, injected intramuscularly, gives very satisfactory results if used immediately after exposure. Its protective value is not likely to last for more than 10 days to two weeks. Therefore, if there is a second or continuous contact with a scarlet fever patient, it is well to repeat the dose after ten days. Since a human serum is used, unpleasant reactions need not be feared.

Should the convalescent serum be administered several days after exposure, it is likely to modify the attack of scarlet fever even if it does not prevent it. If convalescent scarlet fever serum is not available, whole blood—preferably from one who is Dick negative—in quantities of 20 c.c. to 30 c.c. may be substituted. Or a prophylactic dose of scarlet fever antitoxin can be used instead.

For many years it has been my opinion that if tonsils and adenoids were removed before children entered school there would be far less scarlet fever. Such a procedure might not lessen susceptibility but it would undoubtedly reduce the opportunities for infection from carriers.

Diphtheria

Diphtheria is more easily subject to control than any other disease with the exception of smallpox. Today it is hard to realize the excessive mortality in the past which prevailed for this infection. Morbidity rates are still too high in many of our states, though great improvement has taken place particularly in the East. In 1921 there were 2,165 admissions for diphtheria at Chicago Municipal Contagious Disease Hospital. Following an intensive immunization campaign only 96 diphtheria patients entered the same institution in 1933.

Local circumstances may possibly influence slightly the time selected for active immunization. Usually nine months is a good age for the undertaking. It is just as well to omit the Schick test and assume that the child is susceptible. For the purpose of conferring immunity we have had toxin-antitoxin, plain toxoid and alum precipitate toxoid. Now the first named is seldom used. Plain toxoid is best given in three doses of 1 c.c. each, three weeks apart. Sometimes 0.5 c.c. is given for the first dose. Injections are made subcutaneously. If alum precipitated toxoid is used instead of plain toxoid, at least two doses of 1 c.c. each should be administered about one month apart.

In recent years there has been an increasing tendency to immunize against more than one disease at the same time and with mixed antigens. This reduces the number of injections required. Ramon in France adopted this plan for diphtheria and tetanus. Combined diphtheria alum precipitated toxoid and tetanus alum precipitated toxoid are now obtainable. The dose is less than originally recommended. Each injection consists of 1 c.c. which is made up of equal parts of the two toxoids. Three doses are administered at from three to four week intervals. When these combined toxoids are administered there is a synergistic action; that is, the antibody response is greater to each toxoid when they are given together than to either one when injected separately. Moreover, unpleasant reactions are said to be no more common when using these combined toxoids than when diphtheria toxoid is given alone. This combined method of immunization is exceptionally valuable and should receive wider attention. If adopted it will often result in lessening anxiety and saving worry about the necessity for giving antitetanic serum. Should an injury occur where the possibility of tetanus must be considered, the administration of 1 c.c. of tetanus toxoid would probably result in approximately seven times as much protection as would be acquired by the injection of 1500 units of antitetanic horse serum, yet no horse serum sensitization would occur.

Still more recently a combination of diphtheria toxoid and pertussis vaccine has been recommended. Sauer advises this be given at seven months of age in three doses of 2 c.c., 2 c.c., and 3 c.c. at three-week intervals. While no synergistic action is claimed for this mixed dose, the results are said to be as good as if immunizations for the two diseases were done separately. The advantage is in the smaller number of injections required.

TUBERCULOSIS—A DISEASE OF OLDER, OCCUPIED MEN

So much emphasis has been placed on tuberculosis as a serious disease of girls and young women that its greater havoc among men has not received the attention that it deserves. As a result of the more rapid decline of tuberculosis in females in this country there are today 132 deaths among males to every 100 deaths in females, and only at ages ten to thirty is the mortality higher in females.—*The Modern Attack on Tuberculosis* by Henry D. Chadwick, M.D. and Alton S. Pope, M.D.

THE TOXEMIAS OF PREGNANCY

JOHN A. HAUGEN, M.D.
Minneapolis, Minnesota

INCLUDED among the toxemias of pregnancy are diseases peculiar to pregnancy and diseases that occur in the nonpregnant as well.

The symptoms, hypertension, albuminuria, and edema represent a syndrome in pregnancy which may be caused by more than one underlying pathological state. In this consideration of the subject, only pregnancy complicated by this symptom complex will be considered. Consequently, hyperemesis gravidarum, acute yellow atrophy of the liver and the many odd pregnancy complications listed among the toxemias will not be included. Also not included are the various forms of blood pressure elevation such as are found in valvular heart disease, hyperthyroidism, et cetera. Hypertension, albuminuria and edema are the classical findings in preëclampsia and eclampsia, the so-called "true" toxemias. They are also found in nephritis, and in pregnancy complicated by essential hypertension or arteriolosclerosis. The relationship of the acute toxemias to the production of permanent hypertension is the phase of the general problem which has been of most interest of late.

These groups of entities do not always occur singly. This is particularly true of the acute toxemias and their frequent superimposition on an already established essential hypertension. For reasons of simplicity the three main groups will be considered individually.

Preëclampsia and Eclampsia

This group of the so-called hypertensive toxemias are peculiar to pregnancy. They occur in patients who, as far as our clinical methods of evaluation are concerned, have normal vascular and renal systems. The high incidence of ultimate permanent hypertension among the group of patients having this complication suggests that these patients may have the substratum for a hypertension which did not become manifest before their toxemia. As yet our clinical methods of evaluation do not permit recognition of this substratum when it is still in the "prehypertension" or subclinical stage. Preëclampsia and eclampsia are considered to be the same entity, varying only in severity. They usually make their appearance in the last trimester of pregnancy. In the absence of permanent vascular or renal pathology, all signs and symptoms disappear by the third postpartum month.

Their etiology still remains obscure. The etiologic agent is thought to arise in the placenta rather than in the fetus. Presumably some substance is liberated which, among other characteristics, causes a rather generalized arteriolar spasm.

In most instances following delivery of the child and placenta, there is a fairly rapid return to normal. Unless vascular or renal pathology were existent before the toxemia or developed during the course of it, most of these patients are left without sequelæ of the disease. Evidence of its presence is usually lacking by the time of the three months' postpartum examination.

The severity of the disease has been adjudged by the arbitrary choosing of blood pressure levels. A systolic pressure over 140 and/or a diastolic pressure over 90 mm. Hg. are accepted as pathological levels. Mild and severe preeclampsia are determined on the basis of the systolic pressure being above or below 160 and/or the diastolic pressure being above or below 100 mm. Hg. If convulsions or coma ensue, the diagnosis becomes eclampsia.

Glomerulonephritis

The term chronic nephritic toxemia has led to considerable confusion. Its use has been largely abandoned because most patients so diagnosed have been shown to have arteriolosclerosis which is indistinguishable from essential hypertension.

Glomerulonephritis presents a very specific problem. It occurs as a complication of pregnancy only coincidentally. There is no evidence to support the theory of relationship between the development of chronic glomerulonephritis and the acute toxemias. Fortunately, acute glomerulonephritis occurs in association with pregnancy only rarely. The added load of pregnancy

Read in Symposium on Obstetrics at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1942.

on kidneys so affected leaves little hope for the patient's survival unless the pregnancy is interrupted. Fortunately many patients recover from acute glomerulonephritis. Following the healing of the acute nephritis, if a chronic glomerulonephritis has not developed, a pregnancy may be again undertaken and will usually progress uneventfully. Chronic glomerulonephritis, on the other hand, never permits complete recovery. Here, also, allowing a pregnancy to continue in a patient so affected would invite certain maternal disaster because of the rapid advancement of the nephritis caused by the added burden of pregnancy.

Essential Hypertension
(Arteriosclerosis)

Of recent years a voluminous literature has appeared on the relationship of pregnancy to permanent hypertensive disease. More specifically the relationship of the acute pregnancy toxemias to this condition has received much attention. The incidence of permanent hypertension among patients who have had the acute toxemias has been shown to be so high that steps toward prevention of essential hypertension have become an integral part of toxemia of pregnancy management.

The finding of an elevated blood pressure in the first months of pregnancy in the absence of other rare and demonstrable causes means arteriolosclerosis. Pregnancy hastens the advancement of the disease. Frequently an acute toxemia becomes superimposed. The functional arteriolar spasm in the latter condition occurring in arterioles already narrowed by permanent sclerosis augments the symptoms markedly. Usually after delivery these patients have basal blood pressure levels higher than before the pregnancy.

Diagnosis of permanent hypertension can usually be made by the finding of the hypertension early in pregnancy and by the observing of the sclerotic process in the arterioles of the ocular fundi. Occasionally the diagnosis cannot be made with certainty until in the puerperium. Persistence of the blood pressure elevation in the remote puerperium in the absence of other causes of hypertension means arteriolosclerosis. The frequency of its occurrence following preëclampsia and eclampsia and the importance of limiting reproductivity in patients having permanent blood pressure elevations makes the necessity for taking postpartum blood pressure readings quite obvious.

Recently ninety-four patients having had a hypertensive toxemia of pregnancy treated at University Hospital five to ten years previously, were re-examined. 45.74 per cent of these patients were found to have arteriolosclerosis.

The importance of recognizing the presence of arteriolosclerosis and in preventing subsequent pregnancies can best be demonstrated by the Johns Hopkins Hospital material. Following a diagnosis of arteriolosclerosis on their obstetric wards, a corrected ten-year mortality rate of 17.5 per cent was demonstrated. Patients in this group that had a subsequent pregnancy, had a corrected mortality of 39.5 per cent.

Conclusions

Thorough physical examination of obstetrical patients early in their pregnancies is imperative. The finding of an elevated blood pressure demands a careful search for the underlying cause in order that proper treatment may be administered. Patients not seen until late in their pregnancies often present a more complicated problem because of frequent superimposition of an acute toxemia on an already developed arteriolosclerosis.

Careful observation of blood pressure levels in the puerperium is of equal importance. In the light of present knowledge, limitation of reproduction is strongly urged in patients with permanent blood pressure elevations.

DEAFNESS IS SOMETIMES DUE TO ALLERGY

Hearing can be improved or restored in some hard of hearing patients by allergic treatment, Dr. Hugh H. Kuhn, of Hammond, Indiana, told the Fifth Annual Forum on Allergy at Cleveland. Not all deafened patients can be helped. In some cases, however, characterized by variation in the degree and time of hearing loss—patients, for example, who hear better on some days and worse on others—the cause may be an unsuspected allergy which causes a swelling of part of the hearing mechanism with consequent loss of some hearing.—*Science News Letter,* January 23, 1943.

USE OF THE SULFONAMIDES IN PREGNANCY

MELVIN B. SINYKIN, M.D.
Minneapolis, Minnesota

WITH the advent of sulfanilamide and its related compounds, almost immediate clinical application was found in the field of obstetrical infections. The dreaded puerperal infections, commonly due to the beta hemolytic streptococci, were found to respond with almost spectacular results and as early as 1937 a marked reduction in fatality rates, even after blood stream invasion, was reported[2] from the isolation division of the Queen Charlotte's Hospital in London, where sulfanilamide and prontosil were used in every case of puerperal sepsis starting in 1936. Since then the discovery of derivative drugs has been so rapid as to make it difficult to determine which drug to use. The newer drugs, especially sulfathiazole and sulfadiazine are much less toxic and possess a bacteriostatic effect upon a much wider range of organisms than does the parent drug, sulfanilamide.

Probably nowhere has the use of sulfonamide drugs been more welcome than in the treatment of puerperal and postabortal infections. The beta hemolytic streptococcus, largely responsible for the severe form of the disease, is almost specifically inhibited in its growth by the sulfonamides, but other organisms such as the nonhemolytic or anerobic streptococci are more resistant. Sulfathiazole and sulfadiazine, in addition to having less of the unpleasant side-reactions of sulfanilamide, attack a wider range of organisms and have thus become the drugs of choice. In the occasional case an idiosyncrasy to these newer drugs may justify the use of sulfonilamide. The only other advantages of the parent drug are: first, it is less expensive, costing about half as much as sulfathiazole and one-fourth as much as sulfadiazine; and, second, it is more soluble, thus obviating the precipitation of crystals that may occur in the urinary tract with the use of the newer drugs. The first advantage mentioned becomes unimportant when human life is held in balance, and the second avoids a danger that can be minimized by methods of control to be mentioned later.

It is essential to start the drug early in the course of infection before bacterial invasion occurs with development of pelvic thrombophlebitis, pelvic abscess, pelvic cellulitis or peritonitis. Tissue changes cannot be reversed once they are established and they act as a protective barrier for the organisms against the effect of the sulfonamides. The invading army must be counter-attacked before it has a chance to fortify its new position.

Sulfonamides should be started as soon as the diagnosis of generative tract infection is made. Following the first twenty-four hours after delivery, a rise of temperature to 100.4° F. or higher on any two days of the immediate puerperium should make the diagnosis probable when extra-genital disease can be eliminated as a possible cause. With the first rise in temperature a culture of the uterine cavity should be taken and the type of infecting organism determined. If the culture is taken within five days of delivery, the information is more reliable than later when secondary invasion from the vagina may confuse the picture. The choice of a sulfonamide drug should be determined by the type of infecting organism. However, when the infection is severe, either sulfathiazole or sulfadiazine may be started before the report of the culture is returned.

At the University of Minnesota Hospitals sulfadiazine has become the drug of choice for almost all obstetrical infections. In addition to being more pleasant to take, it is rapidly absorbed and slowly excreted, and so allows a rapid rise in the blood concentration of the drug and a maintenance of the desired blood level with less frequent dosage. This permits uninterrupted sleep for the patient and decreases the nurses' burden. By the same token blood levels may rise rapidly and frequent determinations of these are necessary to maintain the desired blood level of 10 to 15 mgm. per cent. This level is usually reached when 3 to 4 grams are given as the initial dose followed by 1.0 gm. every four hours for the first 24 hours and 1.0 gm. every six hours thereafter. Sulfathiazole is still the drug of choice when infection is due to the gonococcus or staphylococcus. Dosage is the same and

Read in Symposium on Obstetrics at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1942.

the desired blood leved to be maintained is 6 to 10 mgm. per cent. Blood levels should be checked daily for three to four days, and every second day thereafter. It should be emphasized that the sodium salts of sulfadiazine or sulfathiazole may be given parenterally when necessary, as a 5 per cent solution in distilled water intravenously or as a .3 per cent to .8 per cent solution in saline hypodermically. The injections may be repeated every twelve hours and require frequent blood level determinations for adequate control. Rectal administration is unsatisfactory because of the irregular and unpredictable rate of absorption.

The drugs should be continued in decreased dosage for several days after the temperature has dropped and clinical improvement is manifest. During administration, all possible supportive measures should be used. Small blood transfusions will augment the patient's resistive powers when the infection is severe. Adequate fluid balance should be maintained and recorded, the minimum fluid intake being 3,000 c.c. daily and urinary output best maintained at 1,000 c.c. The latter is important not only as a supportive measure, but to prevent concentration of the urine with its attendant precipitation of crystals of the acetylated sulfonamide.

Although the danger of urinary tract obstruction is believed to be less with sulfadiazine than with sulfathiazole, several cases of anuria due to sulfadiazine have been reported in the literature, two within the last few weeks.[1,4] The mechanism of this anuria production may be obstruction of the convoluted tubules, kidney pelvis, and ureter due to precipitated crystals, combined with toxic degeneration of the lining of the convoluted tubules. The condition may be avoided by discontinuing the drug and forcing fluids when a marked fall in urinary output occurs or with the discovery of red blood cells together with acetylated sulfonamide crystals on microscopic examination of the urine. The appearance of the crystals alone is no indication to stop the drug. If anuria persists, catheterization of the ureters and frequent irrigation of the kidney pelvis is recommended. The crystals are more soluble in alkaline solution. This has led to the suggestion that sodium bicarbonate be given with each dose of sulfathiazole or sulfadiazine to alkalinize the urine and thus make the precipitation of crystals less likely.

Sulfonamide drugs have also been of great value in the treatment of urinary infections during pregnancy and the puerperium. It has long been known that when urinary infection is once established in pregnancy, it is nearly impossible to sterilize the urinary tract with the ordinary urinary antiseptics such as methanamine or mandelic acid. The sulfonamide drugs, sulfadiazine and sulfathiazole in particular, now permit complete elimination of the usual infecting organisms in most cases, when dosage of 1 gm. every six or eight hours is given for a period of ten days. The desired blood level when sulfadiazine is given is 5 to 8 mgm. per cent and for sulfathiazole 3 to 5 mgm. per cent. In more severe cases the sepsis dosage may be necessary. The colon bacillus group is readily eliminated from the urine but an occasional case due to infection with the streptococcus fecalis, streptococcus proteus, or streptococcus viridans may be resistant even with maximal dosage of sulfonamides. In such cases reversion to mandelic acid or methenamine may be more effective. Clinical cures should not be accepted as final. The catheterized urine should be cultured after the course of therapy and three negative cultures at monthly intervals used as a criterion of cure. This is demanded by the frequency with which chronic changes occur in the urinary tract following pyelocystitis of pregnancy.

Cultures of the urine should be taken in every prenatal patient who has a previous history of pyelitis, even though no pus can be found in the urine. If the culture is positive, a course of sulfonamide therapy should be given since that patient has a 40 per cent chance of developing pyelitis, even though no pus can be found in the rent attacks have been shown to lead to fibrosis in the wall of the ureter with production of the so-called fixed ureter, and chronic persistent infection of the urinary tract. The treatment of urinary tract infections should be directed toward sterilization of the tissues rather than urine. For this reason dosage should be followed by blood levels rather than urinary levels of the drug. In the occasional case of pyelo-ureteritis during pregnancy, it may be advisable to catheterize the ureters, and when evidence of kidney damage heralds the onset of pyelonephritis, immediate interruption of pregnancy is indicated. Fortunately these radical methods of control are only rarely necessary since the advent of the sulfonamides.

Gonorrhea may now be cured in 90 per cent of cases during pregnancy. Sulfathiazole is the drug of choice and should be given in large dosage—directed to maintenance of a blood level of 7 to 10 mgm. per cent over a period of ten days. The patient is best hospitalized and therapy followed by culture study. This should then be repeated at monthly intervals for three months, each resulting in no growth, before cure is pronounced. Culture for gonococci has been found much more reliable than the smear.

Breast infection may respond to sulfathiazole or sulfadiazine therapy if the drug is started before abscess localization has occurred. At the University Hospital x-ray therapy has been combined with chemotherapy in an attempt to abort breast infections before abscess formation. The results have been favorable in the cases so treated, but it is essential to start treatment within a few hours of onset.

Sulfonamides have been shown to pass through the placental circulation to produce a blood level in the fetus equal to that of the mother. This has not been found harmful to the fetus or newborn and does not constitute a contra-indication to the use of the drugs during pregnancy. However, the potentiality of damage to the fetus is present and one case of hemolytic anemia of the newborn[3] has been attributed to sulfonamides received by the mother before delivery. Transmission of sulfonamide to the infant by nursing occurs in such small concentration that neither therapeutic nor toxic effects are likely.

The prophylactic use of sulfonamides may be of value in cases of prolonged labor, intrapartum infection, or potentially infected abortion. Some investigators have advocated the use of these drugs routinely for several days after delivery, but the results are too questionable and the dangers too real to justify such a widespread procedure.

The local application of sulfonamide powder finds little indication in obstetrics but may be useful in preventing infection in the repair of third degree perineal lacerations extending into the rectum or when local contamination of the peritoneal cavity is suspected at the time of cesarean section.

Whenever large doses of any of the sulfonamide drugs are given, toxic reactions are possible and should be guarded against by every available laboratory facility. Kidney function should be determined by means of a phenol-sulphonephthalein test or blood urea nitrogen and therapy should be preceded by complete blood count and urinalysis, the former repeated every second day and the latter daily. Particular attention should be paid to early signs of hemolytic anemia, agranulocytosis and kidney damage. It should be remembered that the sulfonamides may cause liver damage, and one should proceed with caution when it is necessary to use the drug in the presence of jaundice of hepatic origin. Drug fever has been a bothersome complication, but is fortunately less common since the newer sulfonamides came into use. It should be suspected when a rise in fever occurs in a patient after apparent clinical improvement. The drug should be stopped if no other reason for the fever is demonstrable. This will result in a gradual fall in temperature over the next twenty-four to forty-eight hours. Other toxic manifestations that may result from sulfonamide therapy are dermatitis, peripheral neuritis, toxic psychosis and gastro-intestinal upsets. Whenever a toxic reaction occurs, the patient should be warned of her idiosyncrasy to the sulfonamides for her future protection.

The current Minnesota Maternal Mortality study has revealed some shortcomings in the management of sulfonamide therapy. The most common error was the failure to employ bacteriological study as a control for the choice of sulfonamide used. In most of these cases, facilities for such were available. Unwarranted delay in starting chemotherapy may have been contributory to the fatal issue in at least two cases, while totally inadequate dosage was used in others. In one patient a dose of 5 gr. of sulfonamide four times a day was given for severe puerperal sepsis and in another 45 gr. of sulfathiazole was given rectally, daily, in a patient who finally succumbed to peritonitis following puerperal sepsis. It should be emphasized here that full dosage is imperative if therapeutic results are to be expected. Sulfathiazole was given orally to one patient while nasal suction apparatus was in operation; a rather round-about method of sterilizing the contents of the apparatus.

Finally it is quite apparent that full advantage is not always taken of available laboratory facilities to insure early detection of reactions should they occur. Frequent blood counts and daily

urinalysis should be routine in patients receiving full sepsis dosage.

We should remember that our new therapeutic ally carries a double-edged sword which can be directed against the patient as well as against the disease.

OBSTETRICS IN THE HOME

E. S. PALMERTON, M.D.
Albert Lea, Minnesota

IN the preparation and reading of this paper I am quite aware that a large number of Minnesota doctors deliver women exclusively in hospitals. Literature and research on obstetrics appear to be addressed pretty much to this type of practitioner. If a doctor wishes to inform himself on new steps applicable to home deliveries he is forced to search out infrequent articles, or, what is somewhat disconcerting, a nursing textbook on obstetrics.

With each year passing, a larger percentage of deliveries occurs in hospitals, and this is as it should be. Every doctor wants the general advantages and above all the safety of the hospital for his maternity cases. However, the fact remains that home deliveries form a real and considerable part of many doctors' practices. Is home obstetrics to be considered primitive and regrettable, to be discouraged and stamped out as fast as possible?

For the United States in 1939, the number of home cases almost equaled the hospital cases. Certain states had less than 20 per cent of the mothers delivered in hospitals—Alabama, Arkansas, Kentucky, Mississippi, South Carolina, and West Virginia. At the other end of the list are those with 80 per cent to 90 per cent of mothers being confined in hospitals: Connecticut, New York, Washington, California, Massachusetts and New Jersey. Minnesota's figures for that year were 64 per cent hospital cases, 36 per cent delivered in the home. In 1941, of the 55,622 deliveries in our state, over 15,000, or nearly 28 per cent, were home cases.

Certain areas of our state are sparsely settled and hospital care for the pregnant woman is often impossible. In the more thickly settled areas there will be found certain women who choose to have their babies at home. The chief reason for this is economic. Most of these families are not receiving charity; they proudly and painfully pay necessary expenses. Hospital care which can possibly be avoided is not on their budget. If M.D.s refuse to give these perfectly good patients care in their homes, the grandmother or the neighbor, or (what may be fully as undesirable) the osteopath or chiropractor will take charge. In our county of Freeborn the cultists are delivering a small but persistent percentage of home cases. They are to a certain extent cases which the M.D., some M.D., has cast off politely—I know this to be true from experience. The sloughing, unintentional though it be, of home confinements to the cultists is an obvious menace, for the mother will thereafter go to the man who has delivered her for other conditions for which she or her family may need care.

Those of us physicians, then, who have anything to do with obstetrics in the home have an obligation to make the home case comparable to that in the hospital, first from the standpoint of safety, then, as much as possible, comparable in comfort and convenience for our patients and ourselves. It is perfectly possible to carry many of the recent advances in obstetrics to a home case.

I shall touch upon the following with reference to home delivery, reminding you that I have neither time nor desire to discuss these points fully:

Read in Symposium on Obstetrics at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1942.

1. Maintenance of technique.

2. Variations in management with principal reference to drugs:

(a) Anesthetics and analgesics. (b) Vitamin K. (c) Sulfonamides. (d) Oxytocics.

3. Emergency measures for shock.

4. Training new doctors in home obstetric practice.

Maintenance of Technique.—The home case is usually unaccompanied by the frills but need not be without the essentials of good surgical technique. Sterile supplies ready beforehand range from the large pack, complete with sheets, drapes, gowns and towels safely autoclaved, to virtually nothing. It is worth noting that in the work of the Chicago Maternity Center (of which more later) nothing sterile is carried along to the home except towels, cotton and gauze. Gowns are not used. However, the operators are capped and masked. Gloves and instruments are boiled together. Much use is made of newspapers for ordinary cleanliness, and a cone of newspapers pinned at the foot of the operating table (usually a kitchen table) serves in place of a Kelly pad. The patient is prepared by perineal shaving, and the vulvar area cleansed with green soap, then 1 per cent lysol solution, and finally 1 to 500 bichloride solution. When ready to work a sterile towel is slipped underneath the buttocks, and this area, the vulvar area and the pans of instruments and sterile solutions, constitute the clean areas and every effort is bent to keep them clean.

There is a rather pertinent argument against elaborate draping in the home. The so-called sterile field thus created is not understood by lay helpers, and it is almost sure to be contaminated when the physician is not looking. Unless the personnel is trusted by the doctor he might better leave thighs and abdomen bare than have them covered by clean sheets he knows are not sterile.

In some counties in this state, the Red Cross or the county nurse supervises the putting up of packs for home confinements. These are usually autoclaved without charge in a nearby hospital. If autoclaving of such bundles is not possible, they may be baked in an oven for two hours at 320 degrees Fahrenheit. The contents of these bundles vary, but the pack I have used contains two bedpads constructed of newspaper backed on one side with muslin, a half dozen home-made perineal pads, a package of cotton pledgets and a bundle for the baby containing gauze squares, tape and belly band, and a receiving cloth for the baby. A sterile pack of this sort is a great comfort to a doctor no matter what type of home he enters for a confinement; it is especially comforting when he is called, as happens not infrequently, to deliver a perfect stranger in wretched surroundings, the mother having made exactly no preparation for confinement.

Many very good and able physicians do not shave the perineum. These same doctors will shave a portion of the scalp before stitching a laceration there, or they will shave an axilla before removing a gland—surely their logic breaks down when they aver that it is not necessary to shave away the pubic hair.

Throughout a home delivery it is important for the physician to keep from bringing a new strain of organisms into contact with the mother and baby. It is generally held that people are fairly well immunized to their own germs; there is real danger in bringing foreign organisms to them. In this regard it is felt that in many cases the doctor who takes adequate care in the home actually exposes his patient to less risk of foreign infection than if she is delivered in a general hospital, especially a small one where two or three nurses are obligated to care for all types of cases in addition to the maternity group.

Drugs for Anesthesia and Analgesia.—In this regard I have little to say that is new. The doctor usually carries barbiturates, morphine, and scopolamine for analgesia; for anesthesia, ether and chloroform. Chloroform may be required in cases where an open flame is near or the patient has an acute cold. There are types of equipment available whereby nitrous oxide, or even cyclopropane, may be used in the home. I have had no experience with such equipment.

To the above mentioned agents I wish to add with enthusiasm: procaine for local or block anesthesia. This is common enough in hospital work. It can be added very easily to the routine equipment carried to all home cases. Often it does away with the necessity of making use of an inexperienced, frightened anesthetist.

Vitamin K.—The doctor will do well to carry ampoules of one of the water-soluble Vitamin K preparations when he goes to home deliveries.

You know of the discussion pro and con regarding its routine use. I, for one, do not give it to every mother in labor—but use it prophylactically for the instrumental case, the breech, the premature and the infant I fear to be very large.

Sulfonamide Drugs.—I do not intend to discuss the oral use of these drugs, but will mention their local use in lacerations and episiotomies and on the umbilical stump. If a doctor, because of the setup in the home, feels a weakness in his technique, he has a powerful trouble-shooter in sulfanilamide or sulfathiazole powder. If he is caught with the necessity of packing a uterus, he can, in a moment, incorporate one of these substances into the folds of his pack. In order to make available what has been regarded as a brilliant advance in surgical practice in general, the doctor on home confinement has only to take a bottle of the drug along.

Oxytocics.—The doctor conducting a home delivery has a faithful friend in the ampoule of ergot which may on occasion be used intravenously. He should never be without it; its use by vein is not considered dangerous and it should be used after a prolonged second stage with an atonic uterus resulting, after operative delivery with exhaustion or near exhaustion, or after delivery in which the patient has had very much general anesthesia. As for pituitrin, pitocin, thytuitary and the like—these agents have no broader uses in the conduct of labor at home than in the hospital.

Measures for Shock.—I carry a flask of saline with 5 per cent glucose together with a little package of sterile tubing, connections and needles for infusion. This is not expensive—the investment is only about two dollars and it may be very valuable when shock threatens or appears without warning. Plasma may likewise be bought and carried for emergencies—when in the dried state it is stable and need not be kept cool.

Finally, a few words about training new doctors with respect to home deliveries. These points may not be so apropos during the time when most of our medical graduates are joining the armed forces—but when the war is over there will still be home obstetrics.

I had my first home delivery after I had gone into private practice. I am loyal to my school, which is the University of Minnesota; however, I am disappointed in having had no opportunity for training in home obstetrics as a student. Such training gives the student invaluable experience in the following ways:

1. He sees the course of labor more thoroughly than he ever would in a hospital. He gets to know signs of exhaustion and other dangers as they appear instead of leaving them as often happens, for a nurse to discover and announce.

2. His ability to set up and maintain surgical technique is severely tested, much to his eventual benefit.

3. As a corollary to the foregoing, he learns to do without: the best possible light, the greatest possible variety of instruments, and as many pairs of hands as he thinks he needs. Whoever has not repaired a perineum by flashlight, and repaired it satisfactorily, has missed a certain feeling of accomplishment.

The outstanding example of training for home deliveries in this country is the Chicago Maternity Center, a service founded shortly after 1930 and now taking care of 3,000 deliveries a year. In seven years the mortality of the mothers was 1.5 per thousand live births. There was a gross fetal mortality of 3 per cent. Of course, all abnormal cases found in the prenatal clinics are excluded from this home care, and hospitalized. Of those considered normal however, before labor starts, all are delivered in the home, and operative deliveries are done without hesitation when indicated (their operative incidence is 6 per cent). Only those cases complicated by abruptio or previously unrecognized placenta previa are taken in labor to a hospital. Even the acute stages of eclampsia are managed, by choice, in the home. It is obvious that the student who has training on this sort of service will learn technique and self-reliance, if he is capable of learning it under any circumstances.

In conclusion, I have no desire to glorify home obstetrics. The increasing trend in hospitalization of maternity patients is to be desired by all. However, I have attempted to remind the medical profession that home obstetrics is not extinct, nor will it be for a long time. Furthermore, it is possible to bring to the home delivery a large number of the improvements which we have made in obstetric care, as regards technique and preparation for the event of delivery,

as regards certain useful drugs and the measures which we feel must be available wherever there is any likelihood of a patient's going into shock.

Finally, I ask for training in home obstetrics for the medical student, for more than passing attention to this type of practice in the literature, and for appropriate emphasis on the problems of home obstetrics in postgraduate studies.

THE MANAGEMENT OF OCCIPITOPOSTERIOR POSITIONS

WILLIAM C. KEETTEL, M.D.

Obstetrical Consultant, Wisconsin State Board of Health

Madison, Wisconsin

THE most frequent question that is asked me by the general practitioners of Wisconsin is, "How do you handle occiput posteriors?" It is realized that numerous excellent articles have been written on this subject. However, it seems as if many of the more recent articles have tended to confuse rather than to clarify how best to manage this complication. Recently I saw several physicians in rural areas who were greatly alarmed because they had no facilities to make x-ray studies of the pelvis, so they might classify the type of pelvis and in this way know whether to deliver the baby as an occiput posterior or to rotate it to an anterior position should difficulty arise. For this reason it is felt a brief review of the management of this rather common complication might be in order.

The incidence of occipitoposteriors varies greatly; it would seem as if the number reported depends entirely on the time during labor when the diagnosis is made. Calkins,[1] who has made an extensive study of fetal positions, made his initial examination early in the first stage of labor. He reports an almost equal distribution of anterior and posterior positions. On the other hand, when the initial examination is made late in the second stage of labor, the number reported is extremely small, for only the complicated ones, that is those that have failed to rotate, are recognized. The 85 to 90 per cent of occiput posteriors that rotate spontaneously go unrecognized. Because of this fact occipitoposteriors, to many of our physicians, are a dreaded complication.

It is stated by most leading authorities that the head enters the pelvis either in the oblique or in the transverse diameter. Why occiput posteriors occur and why spontaneous rotation to an anterior position does not always take place has been the subject of much speculation. Many theories have been advanced which are beyond the scope of this discussion. Suffice it to say that spontaneous anterior rotation, through an arc of 135 degrees, does occur in 85 to 90 per cent of the cases. This rotation is usually completed during the second stage of labor when the head is on the pelvic floor. To the remaining few that do not rotate spontaneously three things may happen: some will start to rotate but will become arrested in the transverse position; another group will remain either as a right occiput posterior or left occiput posterior; and lastly, a few will rotate posteriorly becoming a persistent occiput posterior, or an occiput sacral position, as it is called by others.

The proper management of a given case begins with the diagnosis of position, and careful abdominal examination is very helpful. Usually one feels the back deep in the right or left flank; the fetal small parts are prominent and are located well anteriorly. The point of maximum intensity of the fetal heart is located most frequently in the flank. However, if the head is not well flexed, the chest will be thrown anteriorly, and then the fetal heart will be heard best in the anterior quadrant of the abdomen.

The course of labor may occasionally give presumptive diagnostic signs, particularly in those cases where the head is slow in rotating. The signs that are most frequently mentioned are early rupture of the membranes, a head that is poorly fixed in the pelvis but not engaged, excessive lumbar pain, and poor, irregular uterine contraction coupled with slow dilation of the cervix. These signs are by no means constant

Read in Symposium on Obstetrics at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 29, 1942.

and are not considered as prominently as they once were.

In addition to the usual findings noted on rectal examinations such as the degree of cervical dilation and effacement and the station of the head, one frequently is able to determine the location of the posterior fontanale and the oblique in which the sagittal suture is located. However, in many instances one is not sure of the diagnosis; for these cases we reserve the sterile vaginal examination to be done when it seems interference is advisable.

Frequently when the caput succedaneum is well formed it is impossible even by vaginal examination to identify for sure the anterior fontanale with its four converging suture lines, or the posterior fontanale directed toward one or the other sacro-iliac synchondrosis. In these cases one feels for the posterior ear, thus determining the position of the occiput. Another procedure that is often helpful is to palpate over the area which you anticipate is the frontal region; if it is, the two frontal bones will give a sensation of crepitation, while the single occipital bone will not. In any of these examinations one must be very careful in estimating the station of the head, for if there is a large caput succedaneum present, the head appears to be more deeply engaged in the pelvis than it actually is.

As many obstetricians have mentioned, the treatment of occipitoposteriors begins during the first stage of labor. This is particularly true when this stage of labor is prolonged. Everything possible should be done to conserve the patient's strength as fatigue is an important factor in uterine inertia, postpartum hemorrhage, and puerperal infection. The woman should receive adequate sedation in safe amounts, using an analgesic drug and not a hypnotic. The fluid and dietary intake should be carefully maintained. The bladder should be watched, and if the patient is not able to void, she should be catheterized regularly. The fetal heart should be checked at regular intervals, as marked irregularity or slowing of the heart between pains is significant.

It is rarely necessary to interfere before the first stage of labor is completed. In fact, it is the conviction of many that a great number of the difficulties encountered are due to attempts at delivery before the cervix is completely dilated. In the rare instances where delivery is necessary before the first stage of labor is completed, one must resort either to the hydrostatic bag, or, if the cervix is well effaced, Dürhssens incisions, to complete the cervical dilatation. Delivery is then effected by forceps or version and extraction. Manual dilation of the cervix is no longer considered a desirable or safe procedure.

Cesarean section is never indicated solely for occiput posterior positions. However, cesarean sections are sometimes necessary where there is some other complication present which necessitates an operative delivery. Then the cesarean section is done because of this complication and not because of the fetal position.

The small number of posteriors that have failed to rotate or have only partially rotated frequently give rise to complications during the second stage of labor, most frequently in the form of prolongation of this stage. However, it is well to remember that anterior positions and face and brow presentation also give rise to prolongation of this stage of labor. When delivery is necessary at this time it is done because of some maternal or fetal complications and not because of the position of the fetal head.

The length of time one should wait in the second stage of labor before interfering has been the subject for much discussion. A favorite expression of Dr. Harris,[2] which is particularly true in these cases, is, "We cannot practice sound obstetrics by the calendar or by the clock." Each patient must be individualized; we must be guided by the condition of the mother and the baby, the progress of labor, and the station of the fetal head.

If the head is high in the pelvis, that is above the ischial spines, we will not interfere until the condition of the mother or baby demands it, or until the head has descended to a lower level. If the head is in the mid-plain of the pelvis or slightly lower, we will interfere if there has been no progress after a reasonable length of time, perhaps two hours. When the head is on the pelvic floor, the time interval will, of course, be shorter. It seems to me that the dictum, "watchful waiting," is most important and in most instances will certainly reduce both maternal and fetal complications, but it might well be amplified to include, "Watchful waiting but never neglect."

When the physician decides that it is necessary to terminate the labor, he determines by a very careful vaginal examination exactly the position of the fetal head. If he finds an occiput pos-

terior, he is confronted with the problem of rotating the head in the safest manner.

It is always best to try manual rotation of the head first, because it is impossible with your hand to produce vaginal tears or trauma to the baby's skull. The difficulty with manual rotation is not the actual rotation but the maintaining of the head in the correct position after the rotation is completed. In order to maintain the head in the correct position several things can be done: (1) place a blade of the forceps beside the baby's head, thus preventing the head from slipping back; (2) place a tenaculum on the baby's scalp; and (3) rotation of the head well beyond the mid-line. The rotation should be done at the level the head has reached in the pelvis, or, if this is not possible, it may be necessary to push the head up slightly. However, one of the main dangers with this procedure is pushing the head too far out of the pelvis, and either losing control of the head, or producing a prolapsed cord.

In a few instances manual rotation will fail, and then one must resort to forceps rotation. The Scanzoni maneuver or double applications of the forceps is the most common method employed. In performing this maneuver one must keep in mind all of the general principles of forceps delivery. In addition there are several other points to consider. The rotation is best accomplished as downward traction is applied; this simulates spontaneous rotation which occurs on the pelvic floor. The handles of the forceps should not be twisted as one twists a piece of rope, but one should always describe a large arc with the handles, thus keeping the head well flexed, and also maintaining the tip of the forceps at a more nearly fixed point. Bill's modification of the Scanzoni maneuver also has many advocates. He maintains that the rotation should be accomplished either at the level of the head or at a slightly higher plane. The Kjelland forceps is advocated by many clinics in the management of the transverse arrests and occiput posteriors. However, the typical Kjelland application, with the rotation of the anterior blade in the uterine cavity, can be a very dangerous procedure if the individual is not thoroughly versed in the use of this instrument. De Lee's "key in lock" maneuver is also used by many physicians with excellent results, but care must be exercised because one blade is placed over the baby's face at some time during this procedure.

Occasionally it may be impossible to rotate the head through 135 degrees to an anterior position; then one tries rotating the head to a posterior position and delivering as such. In such instances one must remember that a larger diameter of the fetal head is presenting and that extensive pelvic lacerations may be produced unless a deep episiotomy is performed. However, delivery as a posterior is necessary infrequently. The only other time it does occur is in the case of mistaken diagnosis, and I may assure you this happens occasionally to most honest obstetricians.

Version and extraction is rarely necessary and is reserved for the patient where the head remains high in the pelvis. In this particular instance version and extraction has replaced the high forceps as the method of choice for delivery.

In conclusion, the important points to remember about occipitoposterior positions are:

1. Spontaneous rotation occurs in a high percentage of cases, often going unrecognized.
2. The diagnosis of position is essential in the proper management.
3. During the first stage of labor interference is rarely indicated.
4. The indications for interference during the second stage of labor are governed by maternal or fetal complications and not by the position of the fetal head, per se.
5. Manual rotation of the head should always be tried before using the forceps as a rotator.

TUBERCULOSIS IN INFANCY

Babies can be infected with tuberculosis during the earliest days of life and such infection in certain cases tends to progress rapidly and often ends fatally. The diagnosis of tuberculous meningitis or generalized tuberculosis in an infant or child should initiate an immediate and intensive search for the source of infection. —A. S. Pope, M.D., *Journal of Pediatrics,* March, 1942.

ECTOPIA CORDIS

H. J. PRENDERGAST, M.D.
Saint Paul, Minnesota

WE feel justified in reporting this case because ectopia cordis is one of the medical rarities. The condition presents such a striking picture and arouses such interest that it is more than likely that all these cases are reported, yet its relative frequency cannot be given with any degree of accuracy. Cosgrove,[3] in 1924, in reporting a case stated that during the twenty years preceding his report not a single case was encountered in the necropsy rooms of the Bellevue Hospital.

In 1938 Ralph N. Barlow, of the Department of Pediatrics, of Washington School of Medicine, reviewed the literature in the *Journal of Pediatrics*, as follows:

"The condition was first described in 1706 by Haller.[5] In 1866 Peacock,[9] cited thirteen cases and reported a fourteenth and in 1904 Ballantyne,[2] mentioned nine additional cases. Cosgrove and St. George,[12] reported a case in 1925, and Wilens and Cutter,[15] reviewed the literature the same year when reporting another case. More recently, in 1936, Kellett,[7] cited eighteen cases and reported a nineteenth. In 1935 Lideny[8] reported a case and in 1936 Wanstrom[13] reported one."

There has been some confusion concerning the exact meaning of the term ectopia cordis, some authors using it to include cases in which the heart is still entirely within the chest cavity but not in the usual position, such as dextrocardia.

Abbott,[1] describes ectopia cordis as "a displacement so that the heart passes out of the thorax and comes to lie either on the outer surface of the body or in the abdominal cavity."

Three types of ectopia cordis have been described according to the location of the heart. Rauchfuss[11] termed them cervical, pectoral and abdominal, while Weese[14] termed them ectopia cordis suprathoracica, ectopia cum sterni fissura, and ectopia cordis subthoracica.

In the pectoral type the lesion is produced by failure of complete development of the sternum. Embryologically, the sternum is formed from bilateral anlages, and failure of the two pieces to fuse causes a fissure sterni with malpositions, principally of the thoracic organs, especially the heart. Schwalbe states that anomalies in the development of the sternum, particularly in the lower animals, is by no means rare and thus anomalous positions of the heart even within the thorax are frequently produced. It is naturally encountered most often in premature or stillborn infants.

Pfaundler and Schlossman[10] state that ectopia of the heart is more of anatomic than of clinical importance. With ectopia the sternum is wholly or partially absent and the skin may be normal or also may be lacking. Ectopia may be an isolated arrest of development or may be but part of an eventration in which the greater portion of the anterior chest and abdominal wall is absent so that the viscera of the thorax and abdomen lie outside of the body. Both ectopia, in which the heart may be covered by pericardium or be completely uncovered, and eventration make it impossible for the child to live.

Cervical and pectoral hearts are considered incompatible with life although infants with the pectoral type may live for several days.

Abdominal hearts are considered compatible with life. Holmes[6] reports an infant that lived for fifteen months to die of empyema. Deschamps[4] reported a case of a healthy soldier whose heart occupied the position of the left kidney.

Case Report

Mrs. H. S., aged twenty-eight, was first seen in her pregnancy on May 28, 1941, at which time she stated that she had not menstruated since April 17, 1941. In 1931 she had had a thyroidectomy, and in May of 1937 she delivered a normal female infant. No history was obtainable of deformities or abnormalities on either her or her husband's side. Pregnancy was uneventful. On January 10, 1942, the fetal heart 122 per minute was heard just to the right of the midline below the navel. On January 29, 1942, she was admitted to St. Joseph's Hospital. The fetal heart 132 per minute was heard in the midline just below the navel during the first stage of labor at 5:30 P.M. After a moderately short labor she was delivered of a live female infant. The presentation was that of a frank

Read before the Ramsey County Medical Society, St. Paul, Minnesota, March 30, 1942.

breech, delivery sacrum right anterior. With the delivery of the legs, a large bluish pulsating mass was felt at the navel. After completion of the delivery we were better able to visualize the abnormality which consisted of a midline defect of the lower anterior chest wall and the upper abdominal wall through which a large mass extended. The extruded mass contained a large pulsating tumor in the superior part and a part of the liver and some bowel in its lower part. The cord was attached at the inferior margin of the defect which measured about 2.5 inches in length and 1.75 inches in width. The infant breathed promptly and color of the skin was good; no other congenital defects were observed. The baby was quite cyanotic at times during the first day and this became increasingly more pronounced so that during the third day of life oxygen inhalations were almost continuous. Its temperature was subnormal throughout its life. The baby took small amounts of glucose and expelled some meconium. Death occurred in sixty-five hours.

Motion pictures, x-ray studies and electrocardiac graphic studies were made and we were fortunate in obtaining permission for a post-mortem examination.

X-rays were taken in the anteroposterior and lateral positions. These show the skeletal development to be complete. The lateral view shows omphalocele containing the heart, liver and the transverse colon.

Treatment.—Cases have been reported in which operations have been performed but in no case has there been a satisfactory result. As this infant showed a cardiac difficulty, as evidenced by cyanosis, it was felt that an operation was contraindicated until she had shown a weight gain and an ability of the gastro-intestinal tract and the cardiovascular system to function efficiently over a period of time, perhaps a month. The presence of one anomaly would cause one to expect others.

Autopsy

External Appearance.—The body is that of a fairly well developed white female infant, length 49 centimeters, weight 2715 grams. There is no edema or jaundice. There is moderate dorsal hypostasis. There is slight cyanosis of the nail beds and of the lips. There is a defect in the anterior abdominal wall measuring about 7 by 4 centimeters. This defect begins just below the xiphoid and terminates at the level of the umbilicus. The umbilicus appears to be incorporated in the defect. Covering this defect is a membrane which appears to be rather thin. Protruding in a hernia-like fashion is a portion of the heart and the liver filling in this defect.

Pleural Cavities.—Upon opening the pleural cavities the heart is noted to be pushing the diaphragm downward and producing the herniation just below the xiphoid process. The heart is above the diaphragm and the liver below it. There is no defect of the diaphragm. The vessels leading from the heart appear to be markedly elongated. On examining the external surface of the heart there appears to be a marked dilation of the right auricle. The heart measures 6 centimeters from the tip of the auricle to the apex of the ventricle. The heart is about 3.5 centimeters wide. At the junction between the right auricle and the ventricle the costal cartilage of the rib is firmly adherent and seems to produce a constriction between the auricle and ventricle at this point. There are adhesions between the anterior abdominal wall and the right ventricle. The adhesions are vascular. Upon closer examination of the heart the right auricle gives the appearance of a balloon with its narrow constricted portion at the junction of the auricle with the ventricle.

Heart.—The heart weighs 31 grams. On opening the dilated right auricle it is noted that there is no communication of the right auricle with the right ventricle. The only communication this portion of the heart has with any other portion is through what appears to be a foramen ovale which has a perforated appearance and bulges into the left auricle a distance of a centimeter or more. There is a remnant of a valve present in the wall of this right auricle but does not appear to serve any function as blood can go to either side of the valve. The left auricle does not communicate with its corresponding ventricle but there is a direct communication of the left auricle with the right ventricle. The right ventricle appears to be dilated. There is a defect in the ventricular septum so that blood in the right ventricle may go through to the left ventricle. Blood in the right ventricle goes out the aorta. Blood in the left ventricle goes out the pulmonary artery. The coronary arteries arise from the aorta which in turn leads from the dilated right ventricle. From the anatomical arrangement of the heart the blood would appear to go in the following directions: blood returning from the peripheral circulation enters the right auricle; from this point it passes through a patent foramen ovale into the left auricle. From here the blood passes to the right ventricle. From there it goes in two directions, some going out the aorta and some going through the ventricular defect into the left ventricle and from there through the pulmonary artery to the lungs. Blood returning from the lungs to the left auricle proceeds directly into the right ventricle. There is some fluid in each pleural cavity. There appears to be some encroachment of the right auricle upon the right lung.

Lungs.—The right lung weighs 20 grams, the left lung 18 grams. On sectioning, both appear to have a moderate amount of edema present.

Liver.—The liver weighs 110 grams. The external surface appears normal. On sectioning, no significant lesions are noted.

Spleen.—The spleen weighs 5 grams. There are no lesions of importance.

Kidneys.—Both kidneys together weigh 37 grams. The external surfaces appear normal. There are no defects noted. The pelves and ureters appear within

normal limits. The pancreas and adrenals appear normal. There are no lesions in the genital tract. The aorta appears to be within normal limits.

Head.—The scalp and calvarium do not show any abnormalities. On sectioning the cerebrum a few areas of petechial hemorrhage are noted in the mid-portion. There are no lesions in the cerebellum or pons.

Microscopic Examination

Lungs.—There is some congestion and pulmonary edema.

Liver.—There appears to be an acute congestion present.

Diagnosis.—(1) Ectopia cordis abdominalis; (2) Pulmonary edema; (3) Passive congestion of the liver.

EMBRYOLOGY AND GENETICS IN ECTOPIA CORDIS ABDOMINALIS

F. C. SCHULDT, M.D.

Saint Paul, Minnesota

AFTER the ectodermic and entodermic layers have developed in the early human embryo, there develops between these two layers, irregularly arranged cells, the mesodermic layer.

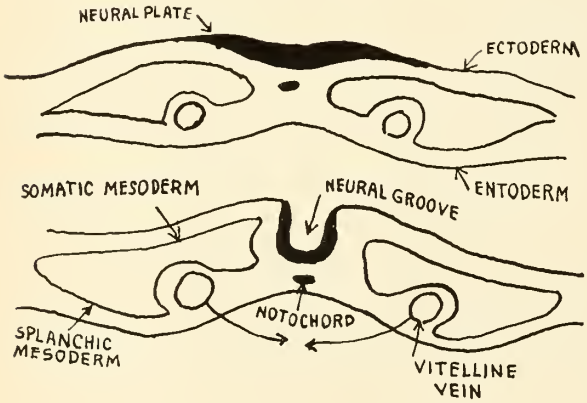

Fig. 1. Early human heart development in its first and second stages.

Very early, in the lateral areas of the embryo a vacuolization develops in the mesodermic layer.[4] These separations of the mesodermic cells extend lengthwise of the embryo and become two laterally placed continuous tubes lined with a single layer of endothelial cells (Fig. 1). These are the vitelline veins destined soon to conduct

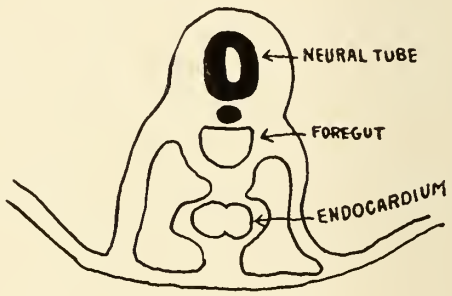

Fig. 2. *(left)* Early heart development in its third stage.

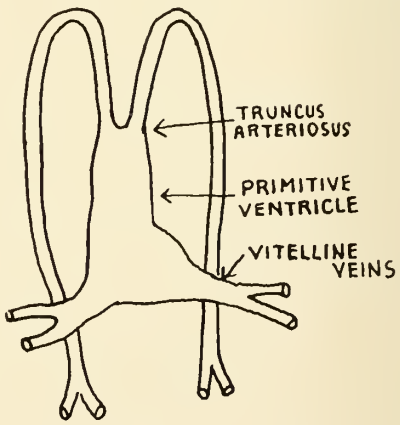

Fig. 3. *(right)* Early heart development in its fourth stage.

the blood stream, the cells of which at this time consist of nucleated red blood cells only. Nu-

cleated red cells are present throughout life in all vertebrates, except in mammals.

These parallel vitelline blood tubes approach toward a ventral median line and unite in the region ventral to the head gut[3] (Fig. 2). In normal development the heart is now one tube, with the venous blood traversing headwards through the primitive ventricle, then through the truncus arteriosus and then into the arched branchial vessels (Fig. 3). This united tube now becomes longer and at the same time the neural tube takes on a rapid growth, causing the embryo, which up to now was straight, to curl, so that the tail comes in contact with the brain tube. There is now a very limited space for an elongating tube to remain straight, therefore it is necessary for it to coil on itself. The venous or atrium portion remains fixed, while the primitive ventricle coils ventrad. At this stage the heart in every embryo appears ectopic. Also at this stage the tongue and brain tube rest immediately upon the heart (Fig. 8d). The heart position might be pronounced to be ectopia cordis cervicalis.

A force of the proper gene is responsible for the rotation of the ventricle to the left chest position. Now we have a uniocular heart, a single chamber with no division. At this time a protusion develops from the posterior wall of the heart tube meeting a similar protrusion from the ventral wall, called endocardial cushions (Fig. 8g). These, uniting, form the septum intermedium which causes a division between the atrium portion and the primitive ventricle, allowing for two communicating channels. Now we have a bilocular heart, the organ of the adult fish and the early heart structure of all air-breathing vertebrates. The next stage is a septum development dividing the atrium into right and left side. Now we have a trilocular heart. The final structural change is the septum dividing the ventricle into right and left, which gives us the normal four chambered heart.

Anomalies of the heart are found in 2.8 per cent of children. As a rule the right half of the heart is the seat of congenital anomalies while the left half of the heart is more often affected by disease in later life.

Predisposing causes of anomaly as given by Birnbaum of Göttingen are: (1) venereal disease; (2) intermarriage; (3) tuberculosis; (4) typhoid; (5) fright during pregnancy; (6) fetal endocarditis.

Congenital anomalies of the heart position are: (1) dextrocardia; (2) ectopia cordis (cervicalis-pectoralis-abdominalis).

The case which was reported by Dr. Prendergast* (Fig. 9), is one of a double congenital heart anomaly: (1) an anomaly of position in that it is an ectopia cordis abdominalis (Fig. 10) and (2) an anomaly of structure (Fig. 11). The anomaly of structure is multiple and consists of:

1. Transposition of the aorta and pulmonary artery.
2. Failure of ventricles to rotate.
3. Absence of mitral and tricuspid valves.
4. A partial mitral valve (useless) on the wall of the right atrium.

*Dr. Prendergast's report appears just previous to this article.

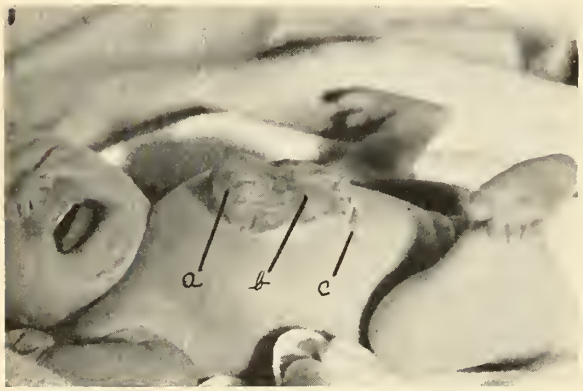

Fig. 9. Infant with ectopia cordis. (a) the ventricles; (b) the colon and liver; (c) the umbilical cord.

5. No communication between the right atrium and right ventricle.

6. No communication between the left atrium and left ventricle.

7. Absence of a ductus arteriosus.

8. Only one coronary artery.

9. Three foramina ovalæ in the interatrial septum.

10. One large opening in the interventricular septum.

11. A diagonal passage from the left atrium to the right ventricle.

12. A very long ascending aorta.

A superficial examination of the baby showed a well developed average new born. The color was good and there were no other deformities. The head and face development was very good. So that one may conclude that the intrauterine existence of the fetus had not been handicapped by all the abnormalities. The circulation apparently had been adequate. For about twelve hours after birth the color remained good. The baby cried occasionally and kicked its legs about like a normal child. The baby did not seem to be in any distress. A colored movie demonstrates this. Later the baby became cyanosed.

Birnbaum classifies single malformations into five classes:

1. Malformations due to arrest of development: fissures, fusion of organs.

2. Malformations due to excess of development: fingers, toes, teeth, ribs, etc.

3. Malformations due to displacement of tissues and persistance of fetal structures: teratomata, dermoids and cysts.

4. Malformations due to errors of development: transposition of viscera.

5. Malformations due to fusion of sexual characters: hermaphroditism.

Death and lethal factors begin at the time the ovum is fertilized. There are many disturbing influences to the developing fetus which depend either upon internal causes or the action of external influences. A trauma to the abdomen severe enough to cause a hemorrhage to the early embryo would cause a deformity. Disease of the parent such as myxedema, severe nephritis, infectious diseases as typhoid and certain poisons may cause developmental deformities. In the majority of cases death and abortion results. Psychic causes are questionable.

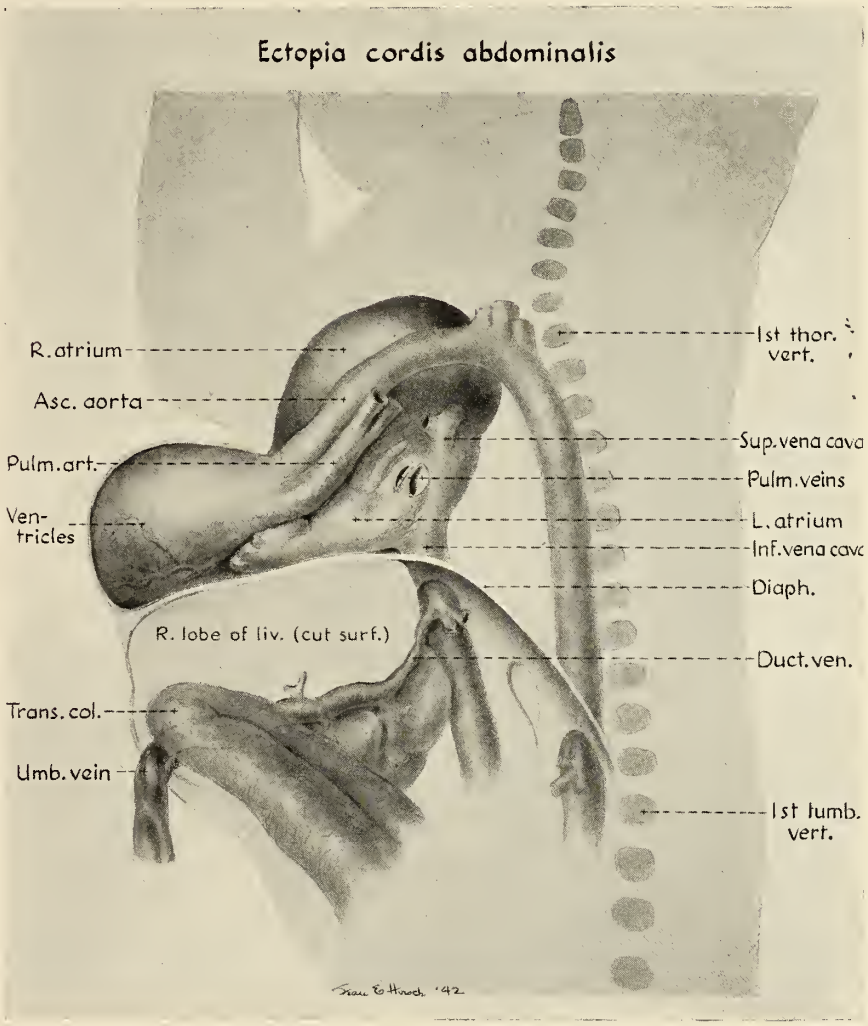

Fig. 10. Ectopia cordis abdominalis.

Very early the amnion lies in contact with the embryo while separation from it takes place later by the formation of amniotic fluid. This liquor amnii may be deficient, may be present in normal amount, or in excess as in hydramnios. If deficient, as the embryo develops and thereby causes a separation of the amnion from itself there remain agglutinations of the surfaces, and as growth continues the embryo finds itself entwined in a mesh of amniotic adhesions, to which may be attributed such developmental deficiencies as are found about the head and in the limbs as amputations. These bands are called Simonart's ligaments. These bands are simple epithelial adhesions or agglutinations and are not inflammatory. In one case of ectopia cordis amniotic bands could be demonstrated on the ventricle as if they had been a causative factor.

Some malformations such as achrondroplasia, albinism or hemophilia, are due to inherited tendencies either dominant or recessive.

In attempting to explain another cause why

anomalies occur, some speculative hypotheses will be expressed, which, though logical, have not been entirely accepted. Such terms as malformation, errors in development, arrested development and transposition have been used in the literature to express the cause of anomalies. Such terms have the faculty of putting a finale on scientific thought as to what forces were active or wanting in bringing about a maldevelopment as contrasted to the normal. When a flower is in full bloom or a large ear of corn hangs on a stalk we admire the beauty of such growth but genetically we must admit that there must have been multiple and varied forces at work to develop such color and fragrance and beauty in the flower and a certain process of chemistry in the carbohydrate development of the corn to produce a fullness of formation in every kernel. Compare this to imperfections in flower development or imperfect kernels or partially developed kernels in the corn, and it is conceivable that some forces were lacking and this can be found in the chromosome and gene structure. Translocations take place in the chromosomes and mutations in the genes, to bring about irregularities in the structure which the chromosome is prepared to build when in normal alignment. So we find a kernel in the ear of corn might have a properly fertilized ovum but something went wrong in the fertilization of the endosperm.

Studies have been made for years in the drosophila melanogaster, the common fruit fly. In-

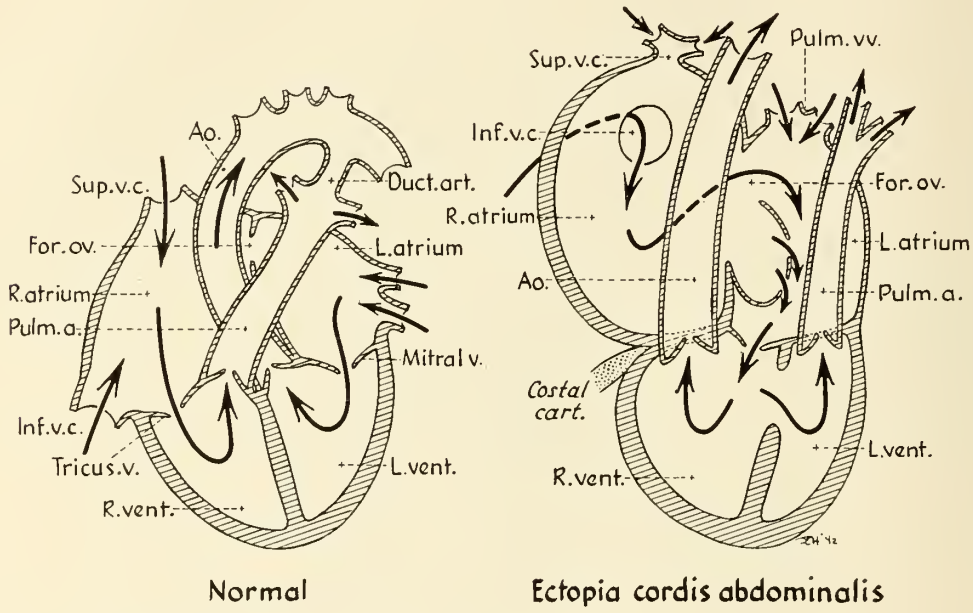

Fig. 11. Line drawings showing circulation in normal conditions and in ectopia cordis abdominalis.

asmuch as the fruit fly produces twelve generations in a year, x-ray and radium effects can be so easily studied and the changes observed. The salivary gland of the maggot of the fruit fly lends itself so readily to such studies. Here we find a definite translocated part of one chromosome attaching itself to another chromosome, and in so doing distorting the development of that portion of the fly structure which such fragment of chromosome was assigned to. Such a translocation can be seen in the photomicrograph (Fig. 6) where a fragment of chromosome number three has attached itself to the x chromosome and there will be an anomaly in the fly, probably lethal. The human being does not lend itself so readily to research and laboratory studies, since a student in genetics would have to live a long life to study the anomaly in two generations. Although there are only four pairs of chromosomes in the drosophila, there are five hundred pairs of factors known.

It seems reasonable to suppose that as vitamins are the exogenous hormones, and the hormones of the endocrine glands control the mechanism

of the developed body, it follows then that the hormones of the intracellular genes control the mechanism of development.[2]

We have learned in the past twenty years of the great potentiality of insulin, a polypeptid which is easily digested. Because the chemistry of insulin of fish, dog and man are identical, allergy is no problem. But we know that if we have an excess of insulin or a deficiency, the mechanism of the body is badly disturbed. Hyalinization of the islands of Langerhans may be the answer, or a tumor may be present.

Thyroxine has a definite force, regulating the oxygen requirement in the body mechanism. An imbalance can take place. An underdeveloped gland may exert an insufficient force to provide the body with enough oxygen, while a pathologic condition might provide a great excess of oxygen to the body. In a similar manner an imbalance of other endocrine glands like the suprarenals, the pituitary, the testicle, the ovary and the parathyroids may act as a misdirected force and may be lethal.

In a very similar way the genes, which are placed in a linear position on the framework of the chromosome, exert a dynamic force and reproduce their kind. Chemically, the transverse striations, seen on the salivary gland chromosome of the drosophila are nucleoproteids. Whether these microscopically visible bodies are the genes, no geneticist will venture to say, but they will admit that these bodies of nucleoproteids are the loci of the genes. Whether the force exerted is a purely chemical one or whether there is an electric influence, or whether there is a combination of these forces, no writer in genetics will mention.

This force may have a normal exercise and a normal being, without a visible defect, will be developed. This means that all the component genes have functioned without failure and every portion of the developed organism is normal.

The force may be dynamic but misapplied or misdirected and an ectopic heart or an anomalus heart structure may develop because of mutation of genes or translocation of a portion of one chromosome upon another chromosome. In our case this was lethal. The force may be deficient or wanting and a hair lip or cleft palate or extrophy of the bladder appear in the newborn infant.

Chemistry and physics have long ago gone through their trial years and are now well accepted in their field. The next science to take its bow to the world is genetics. It already has made big strides and has proven its dignity in the lineup of the sciences.

AMERICAN ATABRINE PROVES IDENTICAL TO FOREIGN DRUG

Controversy over whether atabrine, the antimalarial just made official in this country, is identical and equal to the original product developed in Germany, has now been settled in favor of America's chemists.

A report issued by the National Research Council establishes the fact that the drug manufactured in this country is comparable in every respect with that produced in other countries, according to the *Journal of the American Medical Association* (November 14).

Atabrine, chemically known as quinacrine, is now in mass production as a substitute for war-scarce quinine using the process developed abroad. But chemists here have also found their way through the intricate steps of chemical synthesis which produce the bright yellow crystals used to combat malarial fever.

Unpleasant side-actions sometimes accompanying the administration of the drug led to the suspicion that there might be defects in the manufacturing process or impurities present. Doubts have been dispelled by investigations in leading institutions throughout the country which indicate that these minor difficulties are inherent in the atabrine itself, as occurs in many standard medicines.—*Science News Letter,* November 28, 1942.

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL

A. J. Hertzog, M.D., and S. V. Lofsness, M.D.
Pathologists

Presentation of a Case

Dr. Heise: The case is that of a colored woman, forty-seven years old, who entered the Minneapolis General Hospital on October 26, 1942, and expired two days later. She was first seen in this hospital in the surgery department in 1937 because of a lower abdominal mass. A myomatous uterus, a dermoid cyst of the right ovary and the appendix were removed. She had an uneventful convalescence and was discharged after three weeks. She remained in good health until October 25, 1942, when she developed severe pain in the lower abdomen. The pain started rather suddenly, was crampy but persistent, and was present throughout the lower abdomen. She vomited about eight times during the next twenty-four hours, became weak and somewhat confused, and was then brought to the hospital and admitted.

Her temperature on admission was 100.6 degrees, her pulse rate 120, respiratory rate 20 and blood pressure 126/92. She complained of severe abdominal pain, her skin and mouth were dry, she was somewhat confused and appeared very ill. Examination of the head and chest was essentially negative. Her abdomen was diffusely tender and a vague, very tender mass about 10 cm. in diameter was palpable just to the right of the umbilicus. Pelvic examination revealed a green discharge from the cervical stump and moderate diffuse tenderness in the adnexal regions. Her hemoglobin was 102 per cent, her white blood count was 9,500 with 87 per cent neutrophiles, and her B.U.N. was 20 mg. per cent. A urinalysis and Kahn were negative. Smears of the cervical discharge were negative for gonococci. A duodenal suction tube was passed through the nose and she was given intravenous fluids. Shortly after admission a peritoneal puncture was done and a small amount of fluid containing numerous neutrophiles was obtained. An x-ray of the abdomen was essentially negative. She was treated conservatively but her condition rapidly became poorer. The abdominal pain and mass persisted. Her temperature was 102 degrees the next day and rose to 107 degrees before she died on October 28, 1942.

Dr. Hertzog: This woman entered the hospital with signs and symptoms of acute inflammation within the abdomen. We know that she had her appendix removed five years ago, and this is rather late for any complications except those due to adhesions. A peritoneal puncture supported the clinical impression of peritonitis. A vague tender mass was palpable in the mid-abdomen and an abdominal x-ray was negative for free gas. Dr. Peppard, do you have any suggestions?

Dr. Peppard: There are several things to consider, and the first thing that comes to mind is some type of bowel obstruction with progression to peritonitis. The sudden onset, the fact that she has had abdominal surgery, which is often followed by adhesions, and the recent tender mass all lend support to this possibility. Another thing to consider is primary pneumococcic peritonitis. In years past we saw a number of cases of this disease but recently it has been more uncommon. However, it would be difficult to explain the mass on this basis. The other intra-abdominal accidents such as acute pancreatitis, acute cholecystitis and perforated peptic ulcer must be considered. However, about 75 per cent of patients with perforated ulcer show free gas on x-ray within a few hours.

Student: Does the lapse of five years since her operation lessen the likelihood of obstruction due to adhesions?

Dr. Peppard: Not very much. Obstruction from an adhesive band can follow surgery by many years. What did the mass feel like?

Dr. Heise: It was about 10 cm. in diameter, very tender, moderately firm, and it was not fixed.

Dr. Hertzog: What did the surgeons think about this mass?

Dr. Heise: They thought it might be a carcinoma wth perforation.

STUDENT: Why wasn't she operated upon?

DR. HEISE: Because of her poor condition on admission, she was treated conservatively.

DR. HERTZOG: Dr. Heise will now describe the findings of the autopsy and you will note that they are rather unusual.

DR. HEISE: The only significant changes were in the abdominal cavity, except for slight bronchopneumonia in the lower lobe of the right lung. The peritoneum was moderately congested and lustreless, and there was approximately 500 c.c. of purulent, foul-smelling fluid in the peritoneal cavity. Several loops of small bowel were matted together in the mid-abdomen. They were covered by a yellow fibrinous exudate and the slightest disturbance caused pus to exude between them. After separating the loops of bowel, approximately 50 c.c. of pus escaped. The most discolored segment of bowel was in the upper jejunum about 50 cm. beyond the duodenum. In this region there was a diverticulum protruding into the mesentery; it was 4 cm. long, 2 cm. wide and its opening into the jejunum was 8 mm. in diameter. There were two pieces of firm stool in the proximal portion of the diverticulum. The wall of the diverticulum was thin, discolored, friable and covered with pus, but no gross perforation was seen. The intestine was sharply angulated at the diverticulum and above this it was moderately distended. There was a similar but smaller diverticulum 15 cm. further down the bowel but it showed no inflammation. The other organs were essentially normal.

DR. PEPPARD: Diverticula are uncommon in the upper portion of the small bowel, and diverticulitis more so. This explains the mass and the obstruction. We frequently see duodenal diverticula but they seldom cause any trouble. Is the diverticulum in this case comparable to them?

DR. HERTZOG: Dr. Lofsness will discuss this question for us.

DR. LOFSNESS: There are certain regions in the intestine where diverticula are most common, and these are the sigmoid colon, the duodenum and the terminal ileum. In the sigmoid colon, diverticula are seen in approximately 5 per cent of people. They are small and multiple. Usually they are eight to ten millimeters in diameter, have narrow opening into the bowel, and often protrude into the appendices epiploicæ. They seldom extend down into the rectum but occasionally are present in the descending colon. They are most common in older people and seem to be associated with constipation. Recently we had a patient with signs and symptoms of appendicitis, but operation revealed small diverticula of the cecum with acute inflammation; this, however, is quite unusual. In the sigmoid colon, diverticula give no trouble in at least 80 to 90 per cent of people. They sometimes show chronic inflammation with diffuse thickening of the wall and resulting stenosis and obstruction. This lesion is not infrequently misinterpreted as carcinoma. Acute sigmoid diverticulitis is less common. The process is usually sealed off, with local abscess formation and occasional perforation into the bladder.

Meckel's diverticulum occurs in the lower ileum, usually 50 to 100 cm. above the cecum. They are usually less than 10 cm. long and are located on the antimesenteric surface. They are found in one to two per cent of people and are due to persistence of part of the fetal yolk stalk. They sometimes are the site of acute inflammation and simulate appendicitis. Occasionally the mucosa is in part of gastric type with acid formation, and rarely a peptic ulcer forms.

Other diverticula of the small bowel occur into the mesentery. This is probably because the wall is weaker due to the penetration of the blood vessels, and the lack of a peritoneal covering. Our case falls into this group. There are usually only one or a few diverticula, but in some cases dozens are found. They are not unusual at autopsy but rarely cause any trouble.

Diverticula of the duodenum are common, but complications are rare here also, probably because of their relatively wide openings. In the first portion they are usually due to peptic ulcer with healing and scar formation. In the second portion they are apparently congenital, and are often located near the papilla major.

The pathogenesis of this case, and perhaps most cases of diverticulitis, is comparable to that of appendicitis. There is a blind pouch lined by secreting epithelium which becomes obstructed by a fecolith. The accumulating fluid distends the diverticulum, and this pressure reduces the blood flow through the wall, lowering local resistance to the ever-present bacteria.

DR. HERTZOG: We have presented a case of peritonitis of quite unusual etiology. The final anatomical diagnoses are: (1) Acute jejunal diverticulitis; (2) Generalized peritonitis; (3) Bronchopneumonia.

Peanut oil, now being used for cooking and salad oil, is used industrially in shaving lotions, cosmetics, soaps, dyes and axle grease; and medically, among other uses, in massage for infantile paralysis victims.

THE ASIATIC CHOLERA IN SAINT PAUL

JOHN M. ARMSTRONG, M.D.
Saint Paul, Minnesota

(Continued from January Issue)

Now for the cholera—most of the few cases here occurred before the station was ready for use and are unrecorded. On August 14 (a Thursday), the steamer *Canada* arrived from down the river with two sick men aboard, who the clerk reported were just suffering from cholera-morbus, although five had died on the deck on the Sunday previous. The clerk said the men had eaten a large quantity of green apples and buttermilk which had made them ill. The two sick men were removed to some place, now unknown, and the clerk enlightened. Both men recovered. On August 24, the day the Quarantine Station was opened, a Norwegian immigrant named Paul Andreas Anderson, aged sixty years, was taken from a steamboat at the station and died in six hours. Doctor Smith told me he found this man in a moribund condition lying on the lower deck in a pile of filth, having lost about half his weight. No one would go near the man so he himself carried him to the building. The man was hastily buried on the river bank near the station. Shortly after this, two men were taken from a raft on the river to the station, one of them named Williams. They recovered. These were apparently the last patients treated at the station. I can ascertain the case of but one other who had the cholera during this epidemic, a man named Callihan who died September 9 in town. He is the last recorded cholera patient in Saint Paul, although the late Dr. Samuel D. Flagg told me he saw a cholera patient in 1873, and Doctor Stewart agreed with him as to the diagnosis. The Quarantine Station was closed September 19 and cost the city in all about $3,770. Sometime later, when employes of the city went down to remove some of the furniture, it had disappeared. Some few small articles were recovered from two Frenchmen down the river, but the rest were not found and apparently the search for them was not finished. It was apparent that some one knew where they had gone. The next spring a body was found in the river below Pig's Eye. Doctor Smith, as deputy coroner, recognized the body as that of Anderson and again certified as to the cause of death. The high water had washed away his grave. The last instances of cholera in Minnesota occurred in 1873, eleven cases with eight deaths in a Norwegian immigrant family near Willmar.

While this was the end of the Asiatic cholera in Minnesota, it does not quite end the story, as twice since then the subject has been discussed in meetings of the Ramsey County Medical Society. At the meeting of November 24, 1884, C. D. O'Brien appeared before the Society stating his object in coming to the meeting was to get the sentiment of the Society in regard to the danger to be apprehended from a cholera outbreak in the city next summr. He then proceeded to read a communication to the City Council from the health officer, Dr.

H. F. Hoyt, on the sanitary condition of the city and asked what might be done to improve conditions. Mr. O'Brien said he conceived it to be his duty as the executive of the city of Saint Paul to see that everything possible was done in order to protect the people from possible danger. After some discussion, Mayor O'Brien said in order to simplify matters, he would propose three questions to be solved by the Medical Society. First: Is there reasonable apprehension of the cholera coming to the United States and to Saint Paul next summer? Second: What is the present condition of the city as regards sanitation? Third: What is necessary to be done in order to prevent an epidemic here next summer? Dr. A. J. Stone then moved that a committee of two physicians from each ward of the city be appointed to answer the Mayor's questions. Those appointed were:

First Ward.....Dr. Murphy and Dr. Hoyt
Second Ward.....Dr. Jones and Dr. Ritchie
Third Ward.....Dr. Hand and Dr. C. E. Smith
Fourth Ward.....Dr. Leasure and Dr. Sloan
Fifth Ward.....Dr. Beal and Dr. Francis

Whether this committee ever reported and what was done is unrecorded in the Society's minutes.

In 1892 a most disastrous cholera epidemic occurred in Hamburg and on September 14, a special meeting of the Ramsey County Medical Society was held to discuss the situation should the disease reach this county and Saint Paul. Dr. Harold Graff opened the discussion. Dr. David Day, a guest of the evening, said:

"I graduated in 1849 and in the five years following saw a good deal of cholera in the hospitals of Philadelphia and elsewhere . . . Each epidemic of cholera is accompanied by a great deal of vague bowel trouble, the so-called cholerine, and it is somewhat difficult to make a diagnosis at first. I learned, however, to recognize the real cholera by the smell, as it resembles very closely the smell of fresh blood. In the epidemic which occurred in this city some years ago (1866), I think there were not more than twenty cases of real cholera . . . I recollect one instance in which it took every member in several families in our elevated rural district . . . The disease is so rapid in its course that there is absolutely no time for hospital treatment."

Dr. J. H. Murphy said:

"I have lived in this state to see two or three epidemics of cholera . . . I do not apprehend that we shall have very much trouble here, even if it should reach this country."

While this discussion was going on, the *Moravia* was steaming towards New York with cholera aboard, but strict quarantine prevented its spread.

BUBONIC PLAGUE IN 1942

A case of bubonic plague in a two-and-one-half year old baby girl in Siskiyou County, California, has been reported to the U. S. Public Health Service. This is the first case of plague in humans in the United States since the summer of 1941, when two fatal cases occurred in the same county.

The child is expected to recover, thanks apparently to treatment with sulfadiazine. The sulfa drug treatment was started following a telephone call to Dr. Karl Meyer, Hooper Foundation, University of California. Presumably it was advised by Dr. Meyer, since he has reported successful sulfa drug treatment of plague in laboratory animals.

Where the little girl picked up the plague germs is not definitely known. Her father had hauled hay from a region where plague-infected ground squirrels were known to exist, and the child was playing in the hay the day before she got sick. Cats, dogs, mice and wood rats in the barn of the child's home are considered other possible sources of infection, since these might have harbored plague-infected fleas.—*Science News Letter,* December 12, 1942.

HISTORY OF MEDICINE IN DODGE COUNTY*

BY JAMES ECKMAN†
Rochester, Minnesota
and
CHARLES E. BIGELOW, M.D.
Dodge Center, Minnesota

The pioneer physicians were in very truth a virile and faithful lot of men of whom it would be difficult to say too much in praise. They all looked upon their calling as a profession and not a business and were ever more solicitous about the welfare of their patients than they were about the size of their pocketbooks. The art or science of medicine (whichever it may be) has advanced with rapid stride in the last fifty years and the physicians of today are much better informed, and for that reason more efficient, than the physicians and surgeons of earlier days; but with all of their advantages I very much doubt if they are as unselfishly devoted to duty as their predecessors.—SAMUEL LORD, *Recollections of Mantorville*[1] (1919).

THE celebrated John Charles Frémont (1813-1890), "Pathmaker of the West"[2] and first Republican candidate for the presidency, in company with Henry Hastings Sibley (1811-1891) and several others, penetrated to what is now Mantorville in Dodge County in 1838 or 1839.[3]‡ In a dense wood nearby General Sibley shot a large stag: "It being the first capture of elk that had been made by the party, I was naturally somewhat elated at my success."[3] In the course of investigation of the history of medicine in Dodge County, it is interesting to discover that Frémont, then an unknown young man of about twenty-five years, was "in feeble health."[3] The army surgeon at Fort Snelling had advised him to accompany General Sibley on a hunting trip to Iowa as a therapeutic measure, and Sibley was able to report that "Frémont continued to improve daily from the start, and during the prolonged trip he acquired that robustness of constitution which enabled him to endure the exposures and privations to which he was exposed not many years afterward."[3]

Frémont then proceeded eastward to Prairie du Chien to rejoin the well-known French physicist, Joseph Charles Nicollet (1786-1843), one-time associate of Pierre Simon Laplace (1749-1827), and Dominique F. J. Anago (1786-1853), who awaited the youthful huntsman anxiously.[3]

According to Professor Nevins,[2] Frémont never forgot the beauty of Southern Minnesota as he found it in the late thirties of the preceding century:

Forever afterward, Frémont remembered the rare beauty of the prairies as the gradual northern autumn came on, turning the aspen leaves to gold and the cottonwoods to silver, and brightening the far-spreading plain with clumps of sere buffalo grass and vari-colored flowers. The lowlands near the Renville post were sprinkled with purple asters and ablaze with goldenrod, for that year the prairie flowers were exceptionally luxuriant. On clear days the azure sky merged imperceptibly with the remote horizon, and distant objects trembled and loomed till their size could hardly be judged; in the warmth of Indian Summer smoke veiled the far-off swells, and gossamer drove before the breeze.

This probably is a valid description of what is now Southern Minnesota (not specifically the region embraced in Dodge County**) as the first settlers beheld it.

---

*From the History of Science Seminar (Eckman) of Richard E. Scammon, Ph.D., LL.D., Graduate School, University of Minnesota, Minneapolis.

†Division of Publications, the Mayo Clinic.

‡Sibley himself (reference 3) said the year was 1840, but in 1840 Frémont was not in the West. Professor Nevins (reference 2, p. 36, footnote) has written that the year 1838, which Fremont used in his *Memoirs*, should be accepted as the true one, although he noted that the year may have been 1839.

**Without doubt the region now included in Dodge County was well known to Dr. Lafayette Houghton Bunnell (1824-1903) of Winona, Minnesota, who among other exploits discovered the Yosemite Valley of California in March of 1851. For a complete life of this man, see: Kelly, H. A.: Lafayette Houghton Bunnell, M.D., Discoverer of the Yosemite, Ann. Med. Hist., 3:179-193 (summer) 1921.

The Pioneer Era, 1854-1860

The first railway train to turn a wheel in Minnesota was pulled by the diminutive locomotive *William Crooks* from Saint Paul to Saint Anthony in the summer of 1862;[4] the first enduring impress of civilization recorded in what is now Dodge County was made on April 14, 1854,* when "a company of homeseekers arrived at the present site of Mantorville; on the 15th they proceeded as far as Concord and camped for the night."[5] The next day they erected a house at what is now Concord. It was the first habitation in the county.

How then did these people reach the inland fastness of the region now comprising Dodge County? Probably, at Rochester, they took a crude trail westward over the plains from the old stagecoach road which was opened in the early part of 1854 and which ran northward from Dubuque to the Iowa boundary and thence through Carimona,† Chatfield, Rochester, Zumbrota, Cannon Falls and Hastings.[6] As a writer in the *Minnesota Democrat* is said[6] to have observed in 1852: "The best route is from Dubuque north to the Iowa line, and thence into the Blue Earth and Cannon Valleys."

It has been shown[6] that an early Minnesota physician, **Dr. William W. Finch,** was a commissioner who surveyed a territorial road which was laid out to follow the old traders' trail to Faribault's post and the Straight and Cedar Rivers to the Iowa line. Armstrong has shown that Doctor Finch was in practice in Saint Paul before November of 1853,[7] that he was elected treasurer of Steele County in 1861,[8] and that he died in Santa Barbara, California.[8] Not much more is known about him.

The first settlers in Dodge County no doubt traversed the aforementioned stagecoach road from Dubuque, instead of going up the Mississippi River as far as Winona and then striking off westward overland, for there was no road from Winona to Rochester until 1855,[6] although there seems to have been one from Red Wing through Oronoco** and thus into the county. Rochester, in fact, was platted as a town and marked off as a stagecoach station on the same day: July 25, 1854;[6] but the stagecoach road in question was the one, previously referred to, which ran northward from Dubuque.

Larsen,[6] in an admirable study of the region which included Dodge County in the period of its settlement, wrote:

> To the south of those settlements (Saint Paul, Saint Anthony, Fort Snelling, Mendota, Stillwater) was a dense wilderness comprised within a triangle of land bounded by Iowa on the south, the Mississippi on the north and east, and the Minnesota and Blue Earth rivers on the north and west. Since immigrants arriving in Minnesota came first to this Triangle, it naturally was settled early in the territorial period. There was scarcely a trace of human habitation in the interior of the Triangle at the beginning of the fifties. Seminomadic Indians roamed over the region. At the junction of the Straight and Cannon rivers, in what became Rice County, a trader named Alexander Faribault had established a trading post in 1826, and there were temporary posts in other parts of the interior; but with these exceptions the wilderness was unbroken.

---

*Some of the men in the fall of 1853 had in fact penetrated to where Mantorville now stands, but they shortly returned to their homes in either Iowa or Pennsylvania (probably the former state) for the winter, settling permanently in Dodge County on the date named above.

†The Carimona House in what is now Fillmore County was a famous stagecoach inn of the period. Its register is now owned by the Minnesota Historical Society. See reference No. 10.

**Equipment for the *Mantorville Express* was brought by ox team into Dodge County by this route in 1857. At the ford on the Zumbro River near Oronoco some of the equipment fell into the river, thereby "'wetting down' the paper for the first edition." See: History of Winona, Olmsted, and Dodge Counties, together with Biographical Matter, Statistics, Etc., Chicago, H. H. Hill & Co., 1884, p. 1246.

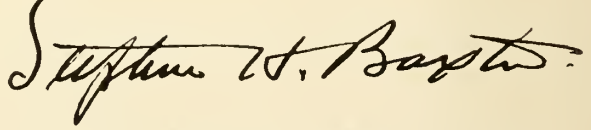
(To be continued in the March issue.)

All references will appear at the end of the completed chapter.

President's Letter

TANGIBLE RESULTS

TIME was, within the memory of many of our older members, when practically the the only source of public information on matters relating to health was found in books like "Dr. Gunn's New Family Physician or Home Book of Health." Built on the generous lines of the family Bible, with gold embossed letters on the back, and a title page setting forth that the book "gives many valuable suggestions for avoiding disease and prolonging life, with plain directions in case of emergency, and pointing out in familiar language the causes, symptoms, treatment and cure of diseases incident to Men, Women and Children, with supplementary treatises on Anatomy, Physiology and Hygiene, and on Domestic and Sanitary Economy," these books were sold by "book agents" who went from house to house. A perusal of these books, even at the present day, discovers much useful and valuable advice, some philosophical in nature, some practical, and it is no part of my purpose to scoff at such books of instruction and guidance. They served a useful purpose in a period when medicine was regarded as something abstract and abstruse, the knowledge of which should be restricted to a select few, and which was shrouded in a certain mystery. This mystery was deepened by illegible prescriptions written in bad Latin, calling for bizarre and exotic drugs. The homely advice and common sense found in such books constituted a large part of the "public health education" of those days, and probably fairly represented the accepted medical practice of the period.



The mystery surrounding medical knowledge and the idea that only graduates in medicine should possess it, held back for many years any systematic or consistent efforts by competent, ethical physicians to educate the public in matters relating to sickness and health. All this is now changed, and private physicians, with the consent and approval of ethical medical organizations, may give popular lectures to all kinds of lay groups on a wide variety of medical subjects. Every avenue by which the public can be reached is now utilized for disseminating medical knowledge, and organized medicine has taken its full share of this task. Window displays have been prepared and distributed, spreading knowledge of cancer, tuberculosis, vaccination and immunization and nutrition. Pamphlets by the thousands have been distributed through doctors' offices giving information on nutrition.

Two radio programs are worthy of notice. Dr. O'Brien's programs combine scientific authenticity and accuracy with a clearness and skill in presentation that make them outstanding in the field of educational programs. Another radio program that deserves notice is called "World Health News," which is sponsored by the Hennepin County Tuberculosis Association. Since April, 1940, this program has given a weekly digest of articles pertaining to health which have appeared in various authoritative medical and scientific publications. The newspapers have done their share in the dissemination of medical knowledge.

Does all this effort pay in the form of tangible results?

A few weeks ago a healthy-appearing young man, twenty years of age, came to a doctor's office asking for a Wassermann test of his blood. Inquiry failed to elicit any history suggestive of syphilis, but the laboratory reported that the blood serum gave a positive reaction. This was confirmed by an independent report from another laboratory. Closer questioning brought out the history of a probable syphilitic infection about three years previously, all signs of which had disappeared spontaneously in a few weeks. Some information which this young man had received recently as a result of the campaign of public health education had recalled to his mind the incidents of three years ago and the result is that he is now taking a course of treatment with a good prospect of being cured.

This, of course, is no isolated case, but merely an example of what is doubtless happening every day in doctors' offices and in homes all over the country. Yes, all our efforts to educate the public to pay; we see fewer neglected, hopeless cases of cancer of the breast; mothers are learning not to give castor oil for the child's "stomach ache;" parents are anxious to have their children vaccinated and tuberculin-tested. The value of some kinds of advertising is difficult to determine, but public health education brings tangible results of great value to the individual and to the community and emphasizes the fact that the medical profession recognizes and is ready to assume its responsibility for the health of the people.

WAR AND DISEASE

DISEASE and pestilence associated with war have caused a greater toll of human life in all wars recorded in history than the conflict itself, with the possible exception of the Russo-Japanese war at the turn of the century. In most wars more of the armed forces have died from disease than from combat and if we include the loss of life in civilian population from pestilence spread by troops or incident to war, the grand total of loss of life from disease greatly exceeds that due to conflict alone.

What can we expect in regard to the factor of disease among our troops in the present world-wide conflict? Our troops are already in every quarter of the globe.

It is true that medical science has made great progress in the discovery of the cause of many diseases which will be encountered by our troops and personnel, their mode of transmission, means of preventing that transmission and specific remedies in a few instances. In the main, however, we shall have to rely on the prevention of infection rather than curative methods. And in war, preventive methods applicable to peace time obviously cannot be carried out.

Universal vaccination against typhoid, smallpox and tetanus is being used for all our troops. Those being sent to the tropics are receiving additional vaccination against yellow fever, typhus and cholera. Troops are being sent to regions where they will encounter malaria plague, amebic and bacillary dysentery, kala-azar, dengue fever, sandfly fever and helminthic infections, against which no vaccinations are available and general sanitary measures constitute the only defense.

Malaria fever constitutes a serious problem. Endemic in the tropics, mosquito control is impossible. Fortunately, the army was well stocked with quinine in advance. While the routine administration of quinine and the equally efficacious atabrine holds malaria symptoms in abeyance, it does not prevent infection and no doubt many troops will return infected with malaria. The anopheles mosquito, the vector of the disease, is widespread in its distribution in this country, including Minnesota, and all we need is a few infected individuals to cause more or less of an epidemic in this state.

Bubonic plague should not prove a serious problem. We know it is spread by the rat flea and rigid measures against the landing of rats at our ports should prevent invasion of our country. We know, however, that there is a focus of the disease amongst the rodents in California which constitutes a constant threat to citizens in that state.

The control of amebic and bacillary dysentry lies in the protection of water and food, an impossibility in certain campaigns.

Fortunately, dengue and sandfly fever, although major causes of disease in some areas, are seldom fatal.

Yellow fever is endemic in South America. The *Aedes Aegypti* mosquito, which is the vector of the disease, is present, however, in the southern states and a few cases could conceivably start an epidemic. The prevention of importation of infected mosquitoes by airplanes arriving from South America is important. Vaccination has been accepted as effective, although certain batches of vaccine produced jaundice weeks to months after administration, with considerable disability, and even a mortality of 0.2 per cent of hospitalized cases. While the cause of the severe reactions has not been completely determined, the elimination of human serum in the preparation of the vaccine seems to have eliminated the reactions. Only troops going to South America and central regions of Africa are inoculated.

Typhus fever can be prevented largely by controlling infestation with the body louse. The disease at present is in evidence on the Russian front and in northern Africa where last year severe epidemics occurred from Morocco to Egypt. The effectiveness of inoculation has yet to be confirmed. We have had small epidemics of typhus fever in this country. Several years ago a number of cases of Brill's disease

appeared in New York City which proved to be typhus. As recent as 1939 one hundred cases of typhus developed in localized areas of Nashville, Tennessee. It seems that endemic typhus is spread by the rat flea and the extermination of rats in certain areas of Nashville terminated the small epidemic.

Cholera resembles typhoid fever in its symptoms and mode of spread. Epidemic invasion of this country by the disease should be easily prevented because of the short incubation time of one to three days and the long period of travel necessary from the Far East to our shores.

Medical science will do more in the present conflict to prevent disease and wounds from exacting as great a toll amongst our armed forces as in previous wars. The sulfo dyes are a valuable addition in the treatment of war wounds. The availability of blood plasma in large amounts for blood replacement is also new and most valuable. We are fortunate in having an enlightened and efficient Medical Corps augumented by more than 40,000 of our best civilian surgeons and medical men who will do much to mitigate the ravages of war and disease.

DOCTOR, SAVE OUR MILEAGE!

CIVILIAN travel by automobile is absolutely essential to the war effort. Seven out of ten industrial workers have to ride to work by private car. Streetcars, trains, and busses can't carry them. The public means of transportation are already overcrowded, and still three-fourths of all travel is by privately-owned automobiles.

So it isn't a question of automobiles or some other form of transportation. For most of us it is a question of automobiles or no transportation at all.

Mileage is being rationed—not because we haven't plenty of gasoline—but because our rubber situation is so extremely critical that drastic measures are necessary to conserve every precious ounce of rubber and every existing tire in the country.

The mileage that remains in our cars and in our tires is essential transportation. To win the war, the country needs this mileage just as it needs steel and aluminum, or planes and ships.

Need the doctor with his "C" book be concerned with mileage rationing? Isn't he in a privileged class so far as gasoline and tires are concerned?

In recognition of the importance from the community standpoint of the doctor's being able to make necessary professional calls, he is made eligible for "preferred mileage" for that purpose and for that purpose only. The law says "for making necessary professional calls outside of his office if he regularly makes such calls and for travel between offices maintained by him."

A doctor is not automatically entitled to a "C" book. The type of ration coupon book he receives depends primarily on the mileage he actually needs for making necessary professional calls. Some doctors will need less than others. The professional needs of some doctors can be taken care of within the occupational mileage of 470 miles per month afforded by a "B" book. Whether the doctor's car carries a "B" sticker or a "C" sticker, he is allowed only 90 miles of personal and family driving per month, because anyone receiving either a "B" or a "C" book and sticker is expected to use 150 of the 240 miles of driving a month on his "A" book for occupational purposes. And if there is a second car in the family not being used principally for someone else's occupational driving, the doctor is expected to use that to the extent of 150 miles per month with its "A" book.

Except for the "preferred mileage" allowed for the making of necessary professional calls, the doctor has no greater driving privileges than his layman neighbor—and properly so.

There is a notion, more widespread among layman than among doctors, that a "C" sticker on the windshield of a doctor's car means unlimited personal driving not only for the doctor but for all other members of the doctor's family. It is regrettable if any doctors, unintentionally or otherwise, have overstated their actual mileage needs for making necessary professional calls and permitted the use of their cars to lend credence to any such notion. Such practices will only reflect against the integrity of the individual doctor and the standing of the profession.

Tires are what the new mileage rationing program is designed to conserve. With the available supply of new regular tires being rapidly diminished, the emphasis is laid on the care and preservation of our present tires, on the prolonging of their useful lives through reduction in speed, periodic inspections, and timely recap-

ping as needed. Where, through no fault of the car owner a tire must be replaced, the type of replacement tire allowed for the particular car depends upon the mileage which has been allotted. The holder of an "A" book only or the holder of an "A" and a "B" book may be eligible for a so-called Grade III tire, which is either a used tire, a recapped tire, or a War tire made of reclaimed rubber. The "C" book holder, when eligible for a replacement tire, may receive a new Grade II or Grade I "pre-war" tire depending on whether his allowed mileage is more or less than 1,000 miles per month.

Applications for tires or recapping services are made with the Local War Price and Rationing Boards. These Boards receive very limited monthly quotas of tires which they cannot exceed, so eligibility for a replacement tire in no way gives any assurance that a tire may be received. This is an additional reason for taking the very best care of one's present tires.

We are assured that every effort will be made to provide doctors with tires needed for making necessary professional calls. Because of the war emergency, no better grade tire and no more rubber can be provided than is absolutely needed for essential travel.

Transportation is a vital war commodity. Doctors can and will do their part in eliminating nonessential mileage.

HUGH W. BROOKS
Office of Price Administration
State Rationing Attorney

WITH CLUBS IT'S LEGAL

A farmer or other producer hauling his produce into New York City must stop at the city line to take on and pay a member of the local teamsters' union. Truck owners who have resisted paying this tribute have suffered damage to their vehicles and the destruction of their cargoes. The Supreme Court of the United States recently ruled that so far as federal statutes went these union activities were perfectly legal and the federal Government could not interfere with them. The consumers of New York pay this union tribute in higher prices.

Organized physicians in the city of Washington, D. C., conspired to interfere with the operations of a coöperative organization to give cheap medical attention and hospitalization to its members who were Government employes. The physicians were charged with attempting to prevent the members of their association from accepting employment under the group health plan and to restrain hospitals from affording facilities to patients of physicians employed under the group plan. The Supreme Court ruled that the organized physicians violated the Sherman anti-trust act.

We do not raise the question as to whether the court correctly interpreted the law in each case.

Apparently the Washington physicians went about this thing in the wrong way. They should have organized a union. The union officials would then hire a group of plug-uglies. These goons could then have beaten up the physicians who did not conform to union rules. They could have picketed the hospitals and refused to let supplies be taken to them.

In all of these activities they would have been immune from federal prosecution. Of course, the local police might have become inquisitive but who in recent years has heard of local police daring to interfere with the activities of union picket lines? What reason is there to believe that Washington, where unions have such powerful friends, would be an exception?

Well, at any rate the good doctors of Washington now know who constitute the "underprivileged."—*Wall Street Journal,* December 20, 1942.

THE TAX ON NON-GIVING

Every minister and every church finance committee should understand the interrelation of taxes and giving.

The important fact is that (up to 15 per cent of his taxable income) the American citizen's gifts represent an *untaxed* part of his income, 100 per cent at his own disposal. It is a long-accepted principle of income taxation that the impulse to give to social and religious purposes should not be penalized by taxation.

Under the new high tax schedules this is more important than ever before. A part of every dollar given to religious, charitable, educational and similar institutions is money which would otherwise go to the Collector of Internal Revenue, the part varying from 24 per cent on an $800 net income or 31 per cent on a $5,000 net income, to 51 per cent on a $15,000 income and 88 per cent on a $100,000 income.

Put in another way, it may be said that the government contributes a part of every dollar disbursed as such gifts. To illustrate: Mr. X, having a net income of $2,000, considers a $100 gift to the church; decides against it; keeps the $100. The tax collector, however, takes $24.00 of the $100. Mr. X retains the balance, but it is then clear to him that if he had made the gift, $24 of it would in effect have been absorbed by the Treasury.

Even more striking is the fact that in the same way a corporation subject to excess profits tax makes a contribution of $1,000 at a net cost to itself of only $190, the balance of $810 being the sum which would otherwise be paid in taxes.

We are not emphasizing tax avoidance; we are stressing the fact that the work of the church is supremely important, its financial support essential, and that the government encourages giving by allowing an equivalent deduction from taxable income up to a limit of 15 per cent of net total income. The same principle applies in Canada.

Between now and the year-end, remind your friends that there is a heavy tax on "non-giving"!—*Ministers Life and Casualty Call,* December, 1942.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

PLANNING FOR THE FUTURE OF MEDICINE

POSTWAR planning requires no coupons. It is not a rationed indulgence and statesmen, economists, scientists, editors and philosophers are all busy sketching their own pictures of the world to come. Some of these pictures are obviously in the realm of fantasy. But all assume, as a matter of course, that great changes are inevitable and that they will come about with a speed for which there is no recorded precedent in history.

We are virtually promised a new era in transportation as soon as the treaties are signed—rear-engined automobiles of unimagined performance and private planes which rise vertically into the air from backyard hangars.

Governor Stassen proposes a world parliament and a world police force to keep men at peace and trade lanes open.

"Production for Employment"

President Roosevelt is said, on good authority, to be ready to propose a plan for postwar jobs on a scale that would utterly eclipse WPA in its heydey. The motto will be "production for employment," not production for profit and every industry will be required to hire its allotment of workers regardless of funds to meet the payroll. If profits are lacking the government will step in and buy the goods.

No major prophet in America has so far blueprinted medicine in this world to come. But minor prophets with plans for a new era in medicine are legion. In England, of course, the Beveridge report has already called for vast extensions of health insurance. It envisions government hospitals as health centers of every community after the war.

Will the major planners in America leave medical practice out of their calculations? It seems hardly likely.

True, the new Congress will not be so friendly to social experiment as immediate predecessors. It should be remembered, however, that many a planner in Washington is in a position to give considerable substance to his ideas without benefit of Congress.

Impossible to Ignore

It is true, also, that the end of the war is likely to see a reaction such as followed World War I against war and all of its works. But public reaction will not be able to camouflage the toughest economic problems the world has ever faced. The most reactionary administration it is possible to conceive in Washington will not succeed in ignoring demands for jobs and security from millions of returning soldiers and millions of discharged war workers. Lacking a new continent to develop, some social and economic planning will be forced upon the government in Washington regardless of the complexion of its politics at home. And it is inconceivable that anything so intimately bound up with public welfare as medical service will escape considerable change and adjustment.

Whether qualified physicians or Washington bureaucrats plan these adjustments and put them into effect, depends largely upon the attitudes and policies of physicians themselves, now, as well as later when the crisis is upon them. They too must take a hand in the planning and sit in the counsels of the planners.

Physicians Can Lose

Medical association officials have sometimes appeared in the public eye as mere obstructionists, stubbornly and blindly combating change. It is self-evident that no one wins a battle against time and tide and the forces of social evolution. But by the same token, physicians, their traditions and their standards, can lose and lose trag-

ically if they fail to take a wise and responsible hand in shaping events to come.

For that reason, the program arranged for the 17th National Conference on Medical Services to be held Sunday, February 14, at the Palmer House in Chicago is of the greatest interest and importance.

Medical Participation to be Planned

The program is comprised of two symposiums entitled, respectively, "An Analysis of Current Trends in the Control of Medicine" and "Medicine in the Postwar Era." Medical association officers, delegates and committees from all over the country will engage in these discussions. Out of them should come some realistic and sound policies to guide their participation in the America to come.

Every physician who can possibly spare the time should attend this meeting and take part in these important discussions.

MEDICAL AND HOSPITAL OBSTETRIC AND PEDIATRIC CARE FOR WIVES AND INFANTS OF MEN IN MILITARY SERVICE

Note.—The information printed below was provided by Dr. A. J. Chesley, secretary and executive officer of the Minnesota Department of Health after consultation with the Committee on Child Health and the Council.—The Editors.

The Minnesota Department of Health has a limited fund, in the amount of $10,000, allotted by the United States Children's Bureau under the terms of the Federal Social Security Act, to provide the medical and hospital obstetric and pediatric care needed by the wives and infants of men in the military service. As you will note, only $10,000 is available now and we have no information as to what funds the Children's Bureau may make available in the future. In recognition of the limitations of this fund, it is urged that all claims on it be made with discretion and thoughtfulness. Furthermore, the provisions of this program cannot be made retroactive. Applications will be accepted only for patients currently receiving medical care and until the fund is exhausted.

Eligibility

All expectant mothers living in Minnesota, irrespective of legal residence, who state that the father of the expected child is in military service (U. S. Army or U. S. Navy, including Marine Corps or Coast Guard) and not a commissioned officer, are eligible for financial assistance with medical and hospital obstetric care without cost to the family whenever such care is not available from Army or Navy physicians and hospitals and tax-supported prenatal and pediatric clinics or hospitals. Unmarried expectant mothers will be included in this program in accordance with plans for their care developed by the State Division of Social Welfare and, therefore, the unmarried expectant mother should be referred to the County Welfare Board in the usual manner.

Any child under one year of age living in Minnesota, irrespective of legal residence, whose father is in military service, but not a commissioned officer, is eligible for pediatric medical and hospital care, including well-baby care and care during sickness, without cost to the family whenever such care is not available from Army or Navy physicians and hospitals and tax-supported pediatric clinics or hospitals.

Applications

Applications for these services are to be submitted jointly by the patient and the physician of her choice as soon as possible after care begins.

Three application forms are provided: (1) for medical and/or hospital maternity care; (2) for well-baby medical care; (3) for medical and/or hospital care of child during illness. The last form should be submitted for each individual illness or hospitalization. These forms are obtainable from the Division of Child Welfare, Minnesota Department of Health, University Campus, Minneapolis, and are to be submitted directly to that division.

Authorization

Such applications will be approved for payment when the medical services are to be rendered by Doctors of Medicine licensed in Minnesota by the State Board of Medical Examiners and when hospitalization is to be provided in an institution licensed for the purpose by the Minnesota Department of Health. It is requested that the least expensive available hospital facility be used, i.e., ward beds or semi-private rooms in preference to a private room. Private room care will be authorized for the patient whose condition requires it. Notification that payment is authorized will be sent immediately after approval to

the attending physician, patient, and hospital—if hospital care is recommended by the attending physician. The case will then be referred to the local public health nurse with a request that she contact the attending physician to ascertain whether her services may be of assistance in the care of the patient.

Payments

Payments for medical and hospital care will be made only if previously authorized.

Payments to physicians for medical services will be made by the Division of Child Hygiene, Minnesota Department of Health, at the termination of care and when a satisfactory maternity or pediatric record is submitted on forms supplied for the purpose. These payments will be made in conformity with the fee schedule recommended for use in this program by the Minnesota State Medical Association. The fee schedule is attached herewith.

Payments for hospital obstetric and pediatric care will be made by the Division of Child Hygiene, Minnesota Department of Health, at the per diem rate of the hospital concerned upon receipt of a satisfactory record of services rendered. Forms are supplied for this purpose.

Medical Consultation

Physicians desiring medical consultation in the care of these patients are directed to apply to the County Medical Advisory Committee. The consultant will be paid the fee provided in the attached fee schedule.

MEDICAL FEE SCHEDULE FOR MEDICAL AND HOSPITAL OBSTETRIC AND PEDIATRIC CARE FOR WIVES AND INFANTS OF MEN IN MILITARY SERVICE

From the Schedule of Allowances Approved for the Use of the Division of Social Welfare by the Medical Advisory Committee

The complete fee schedule contains 206 items but only the fees for the usual medical obstetric and infant care procedures are included in this list. Fees for other procedures will be supplied to physicians on request.

General

Call (country, day) per mile $1.00 first ten, then $.50 per mile.	
Call (country, night)—$1.00 plus mileage.	
Call (town, day)	$ 2.00
Call (town, night)	3.00
Call (hospital)	2.00
Call (hospital—out of town doctors)	3.00
Call (office, with 2 laboratory procedures)	2.00
Call (office—routine)	1.00
Consultation (plus mileage charge)	5.00
Intramuscular therapy	2.00
Intravenous therapy	3.00

Obstetrics

Abortion (therapeutic)	50.00
Bag insertion during labor; add to suggested allowance	10.00
Cesarean section	150.00
Delivery, normal, home, plus mileage	25.00
Delivery, normal, hospital	25.00
Ectopic pregnancy	150.00
Forceps delivery; add to suggested allowance	5.00
Miscarriage	25.00
Obstetrical consultation, plus mileage	5.00
Obstetrical version and extraction; additional charge	25.00

Immunizations—Complete Course

Diphtheria	2.00
Smallpox	1.00

Laboratory Work

Basal metabolism rate	5.00
Blood cell count (red)	1.00
Blood cell count (white	1.00
Blood count (differential)	2.00
Blood culture	5.00
Blood sugar (single test)	3.00
Blood sugar (tolerance test)	5.00
Electrocardiogram (including interpretation)	6.00
Hemoglobin determination (Dare, Sahli)	1.00
Phenolsulfonphthalein test	5.00
Sedimentation rate (blood)	3.00
Urinalysis	1.00
Venous blood for diagnostic tests	2.00

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

J. F. Du Bois, M.D., Secretary

Minneapolis Chiropractor Loses Basic Science Certificate and Chiropractic License

Re: State of Minnesota vs. Henry Wuerzinger

On January 12, 1943, Henry Wuerzinger, seventy-nine years of age, residing at 3453 Stevens Avenue South, Minneapolis, entered a plea of guilty in the District Court of Hennepin County, to an information charging him with the crime of practicing medicine without a license. Wuerzinger, a licensed chiropractor, was sentenced by the Honorable A. W. Selover, Judge of the District Court, to a term of one year in the County Jail of Hennepin County. The defendant was placed on probation for three years on the following conditions:

1. Defendant must surrender, for cancellation, his Minnesota Basic Science Certificate and his Minnesota Chiropractic License.
2. The defendant's medical and surgical equipment seized by the Minneapolis Police Department is to be turned over to Minneapolis General Hospital.

3. The promissory note in the sum of $75.00 obtained by the defendant from the patient at the time of the alleged abortion, is to be returned to the patient for cancellation.

Wuerzinger was arrested on October 8, 1942, following an investigation of his activities by the Women's Bureau of the Minneapolis Police Department and a representative of the Minnesota State Board of Medical Examiners. During the course of this investigation a twenty-two-year old unmarried Minneapolis girl stated that Wuerzinger had performed a criminal abortion upon her on June 23, 1942, at his then residence, 3859 Second Avenue South, Minneapolis. The patient stated that Wuerzinger charged her $125.00 in cash, and in addition thereto, demanded a promissory note from her for $75.00 dated July 1, and payable in fifteen days. When the police arrested the defendant at his home they seized Wuerzinger's examining table, surgical instruments, medicinal preparations and other similar articles. The police also discovered in Wuerzinger's possession, the $75.00 note executed by the patient. Following his arraignment in Court, the defendant insisted that he was too sick to stand trial. However, the examining physician stated that Wuerzinger was able to stand trial and the Court ordered the case set for January 12, 1943. Because of the defendant's age and the condition of his health, he was permitted by the Court, upon the recommendation of the County Attorney's Office and the Minnesota State Board of Medical Examiners, to plead guilty to the lesser charge.

Wuerzinger, according to the records of the Minnesota State Board of Medical Examiners, has been in Minnesota since 1907. During many of these years the defendant represented himself as a physician and surgeon, although the only license he ever held in Minnesota was a chiropractic license issued to him in 1919, by exemption. Wuerzinger also received his Basic Science Certificate in the same manner in 1927. He was indicted by the grand jury of Hennepin County in December, 1935, and charged with manslaughter in the first degree following the death of a Hopkins, Minnesota, woman, who stated that Wuerzinger had performed a criminal abortion upon her. Wuerzinger was never brought to trial in that case because of his alleged ill health.

The Minnesota State Board of Medical Examiners wishes to emphasize the splendid work done by the Women's Bureau of the Minneapolis Police Department in this case. The police women, under the able leadership of Lieutenant Blanche Jones, made a thorough investigation into the facts surrounding this case. Because of their vigilance the police discovered the $75.00 promissory note given Wuerzinger by the patient. This was the most valuable single item of evidence obtained by the State. The evidence obtained was undoubtedly a large factor in prompting Wuerzinger to offer to plead guilty to the lesser charge. The Minnesota State Board of Medical Examiners also appreciates the fine spirit of coöperation shown by the new County Attorney of Hennepin County, Mr. Michael J. Dillon, and his assistants, Mr. Peter S. Neilson and Howard Van Lear. Their insistance that his case be tried contributed greatly to the results accomplished.

Minneapolis Abortionist Sentenced to Four-Year Prison Term

Re: State of Minnesota vs. (Mrs.) Sophia Peck

On January 2, 1943, Sophia Peck, sixty-two years of age, was sentenced by the Honorable Frank E. Reed, Judge of the District Court of Hennepin County, to a term of not to exceed 4 years at hard labor in the Women's Reformatory at Shakopee, Minnesota. Mrs. Peck was convicted by a jury on December 3, 1942, of the crime of abortion.

The testimony at the trial showed that the defendant attempted to perform an abortion on an unmarried Minneapolis girl on July 17, 1942, by the use of a rubber catheter. The attempted abortion was a failure and the same procedure was repeated again on September 19, and September 24. The patient became seriously ill and was hospitalized twice in October. She subsequently recovered and testified for the State at the trial. The State also had as evidence catheters, instruments and medicinal preparations seized by the Women's Bureau of the Minneapolis Police Department at the time the defendant was arrested. The defendant told the Court that she was a tailor by occupation but had also engaged in the selling of cosmetics. Mrs. Peck holds no license to practice any form of healing in Minnesota, and at the time of her arrest resided at 59 North 15th Street, Minneapolis. Mrs. Peck was tried for a similar offense in October, 1937, but was found not guilty by a jury.

HEAR DISEASE NO BAR TO INDUSTRIAL EMPLOYMENT

Heart disease need not bar the patient in every case from industrial employment. Many thousands of heart patients and probably most of the 10 per cent or so of young men rejected for the army because of heart and blood vessel disease would qualify physically for positions in industry.

Statements to this effect were made by both Dr. Rufus B. Crain, of Rochester, N. Y., and Dr. O. F. Hedley, of the U. S. Public Health Service, before the committee on cardiac clinics of the New York Tuberculosis and Health Association.

From experience at the Eastman Kodak Company, Dr. Crain reported evidence that "with careful placement and medical supervision" persons with heart disease and high blood pressure "can be continued in employment without risk.

"This experience should encourage the hiring of individuals in the same category as new employes," he declared.

The right to work when physically handicapped is one of the practical, far-reaching gains for labor and society which is being reached through the war and which should be held after the war, Dr. Hedley pointed out.

In the case of heart disease the importance of continuing to make it possible for the patients to work can hardly be exaggerated, because with the aging of the population, the numbers with heart disease will continue to increase.

In the future, society will be faced with the choice of obtaining employment for the increasing group of heart disease patients or otherwise providing a means of livelihood through some form of taxation.—*Science News Letter,* January 30, 1943.

PERSIMMON LEAVES RICH IN VITAMIN C

When tea joins coffee on the list of scarcities, don't worry. Brew yourself a tasty cup from persimmon leaves—if you live where persimmons grow. It's good for you; full of scurvy-preventing vitamin C.

Prof. C. G. Vinson of the University of Missouri and Prof. F. B. Cross of Oklahoma A. and M. College report (*Science,* Nov. 6), that green persimmon leaves are rich in this essential vitamin. Freshly dried leaves sometimes have an even higher concentration. Green fruits also contain the vitamin, though not as much of it as the leaves; the vitamin apparently disappears to a large extent as the fruit ripens.

Tea made from chopped-up dried leaves was found to be a good vitamin source, and tasted rather well with a little sugar—"Similar to sassafras tea." Real tea was also tested, but proved to have only about 7 per cent as much vitamin C as the decoction from persimmon leaves.—*Science News Letter,* November 28, 1942.

FITTING WORKERS TO THEIR JOBS

Clerical workers and executives in industry have probably enjoyed less than their share of benefits from modern medical services in industry according to Dr. T. Lyle Hazlett, medical director of the Westinghouse Electric and Manufacturing company, whose article on the subject, "What Are We Examining For," appeared in the December issue of *Industrial Medicine*.

Executives Studied, Too

Of especial interest was a survey described by Dr. Hazlett of the cardiovascular condition of 692 executives between the ages of 30 and 67 in the Westinghouse employ.

The study included electrocardiograms, blood pressure determinations, fluoroscopy for the study of cardiac contours, cardiac auscultation and urinalysis.

"It was found," Dr. Hazzlett reported, "that over 13 per cent of the group exhibited one or more abnormal findings. Over 11 per cent of the electrocardiograms revealed abnormalities; the blood pressure was found elevated in 7.6 per cent; fluoroscopy revealed abnormal heart contour in 9.2 per cent; auscultation showed four per cent to have significant cardiac murmurs and urinalyses were positive in four per cent. Of the latter, eight cases exhibited glycosuria which had been previously unsuspected. These findings would appear to suggest advisability of universal periodic examinations for workers in all divisions of industry. Such examinations should, as a rule, be of general character and not limited to one system."

Psychiatric Aspect Important

Dr. Hazlett also emphasized the importance of the psychiatric aspect of the industrial medical examination. This phase of the examination deals with the personality type and studies the individual from the point of view of emotional and intellectual traits. It is especially necessary, he believes, in this period of strain. The balanced personality with adequate social adjustments obviously brings to his job and to his vocational contacts qualities which are distinct assets both to his personal contentment and to his vocational success. "At present," he says, "little attention is paid to psychiatric factors; only the most marked abnormalities are apt to strike the examiner's attention.

"I mention this matter as a desirable element to develop in our examinations. Then, in passing, I should like to mention psychological tests of such traits as mechanical aptitudes, skill in certain types of performance, extent of information in certain subjects. These latter tests may well contribute to a more complete knowledge of the individual potentialities."

Pre-Placement Objective

The pre-placement examination, according to Dr. Hazlett, has for its major objective the assurance of the utmost degree of compatibility between the worker and his job, not only from the standpoint of job efficiency but from the standpoint of industrial hazards.

There are two aspects to this question. One deals with physical conditions which may be aggravated by certain types of work and the other with physical defects which will increase the accident hazard not only to the worker himself but to fellow workers as well.

"In the first class," he says, "we find the silicotic patient who, by continued exposure to silica dust, is under greater menace of tuberculous infection than the applicant with reduced vision, abnormal hearing, epilepsy and psychoneurotic traits. It must not be forgotten that, even with the best mechanical safeguards, the possibility of accidents exists and, in the majority of cases, the human factor and not the mechanical one, determines whether an accident will or will not occur. . . . This does not imply that the pre-

Minnesota Academy of Medicine

Meeting of October 14, 1942

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 14, 1942. The meeting was called to order at 7:40 p.m. by the president, Dr. Martin Nordland.

There were forty-eight members and two guests present.

Minutes of the May meeting were read and approved.

The scientific program followed.

THE MEDICAL MANAGEMENT OF PEPTIC ULCER

(Abstract)

MOSES BARRON, M.D.
Minneapolis, Minnesota

Treatment of uncomplicated peptic ulcer is practically always medical. Only certain complications are to be considered surgical. Rarely do the symptoms of uncomplicated ulcer persist after appropriate medical management so that surgery has to be resorted to. Peptic ulcer is one of the common causes of gastric complaints. In people over forty gall bladder causes distress more often than ulcer, especially in women. Most ulcers are duodenal, only about 5 to 6 per cent being gastric. Clinical ulcers are much more common in males than in females, about 85 per cent occurring in males. Gastric ulcers occur more commonly after the age of forty while more than 50 per cent of duodenal occur under the age of thirty. The exact etiology is not known but constitution and heredity are important factors. Many theories have been brought forth to explain ulcer development such as certain vascular changes, alterations in the nerve supply, focal infections and localized trauma from foods. The only almost constant finding associated with ulcers is acidity. Usually this is in excess. The importance of the acid secretion in the formation of clinical ulcers has been demonstrated experimentally by the production of ulcers in laboratory and domestic animals through repeated administration of histamine. Also the hyperacidity resulting from repeated and continuous stimulation of the vagus as well as the acidity induced by sham feeding produce ulcers in dogs. Wolf and Wolff[1] present an interesting study in the development of peptic ulcer in man. They show the relationship of anxiety and conflict to overactivity and hypersecretion in the stomach and the effect of this in turn on the development of ulcer. Such ulcers may finally progress to hemorrhage or perforation. Gastric ulcer may develop in cases of anacidity but these heal without producing clinical symptoms. As an illustration one never finds clinical ulcers developing in patients with pernicious anemia in whom, as is well known, achylia gastrica is always present. Since all ulcers probably start as simple erosions the presence of acid seems to be a factor sine qua non for the prevention of healing. Trauma from food may also be a factor. This is especially true if the gastric contents is projected against a particular area of the mucosa. The bolting of coarse food may add to the difficulty. I believe that not enough attention has been paid to the psychoneurogenic factors. It is quite apparent to everyone dealing with ulcer patients that they constitute a class notoriously highstrung, aggressive, sensitive and irritable. Some authorities claim that there is an association between the development of ulcers and lesions in the region of the pituitary and hypothalamus.

It is an interesting observation that perforations occur in men twenty-five times more frequently than in women. Fatal hemorrhages are also much more common in men. This in view of the fact that careful post-mortem studies of the stomachs have shown that asymptomatic erosions and small ulcers are even more common in young women than in men. They seem to heal before symptoms or chronicity develop.

It has been shown that in the treatment of peptic ulcer if alkali is used the duration of pain averages 2.8 days, but with the same diet, if beef extract is used the average duration of pain is twenty-six days. Worry, nervous strain, exertion and over-work tend to increase gastric secretion and therefore also the pain. The vitamin deficiencies of B_1 and A play apparently an unimportant part in the causation of ulcer. These deficiencies produce hypochlohydria and anorexia. Pure gastric juice has a capacity to destroy and digest living tissues, but when mixed and diluted with gastric contents it becomes practically inert toward such tissues. Whenever there is excessive secretion even during rest the healing of the ulcer is inhibited or delayed.

Pathogenesis.—Peptic erosions are common in many individuals and in the stomach are often multiple. These at first are superficial and heal readily without scarring unless certain factors delay it. Clinical duodenal ulcers occur mostly in males between twenty and fifty years. Most stomach ulcers are on the posterior wall of the lesser curvature, several inches above the pylorus. Duodenal ulcers become deep seated and develop intragastric and perigastric reactions. Since the gastric secretion has a corrosive action in producing the clinical ulcers, treatment resolves itself mostly to reducing and eliminating the acid.

Diagnosis.—Peptic ulcer is a common disease too frequently mismanaged. Too long delayed or improper treatment is probably the greatest cause of the com-

plications which may later necessitate surgical intervention. A careful detailed twenty-four hour history is important for diagnosis. X-ray studies are important to corroborate the diagnosis which can usually be arrived at from a careful history together with gastric analysis. The physical examination reveals little in ulcer except inconstant tenderness in the epigastrium.

Symptoms.—Pain in the epigastrium, gnawing, burning-like hunger pains from one to four hours after meals, with heartburn and gas distress and often sour eructations suggest the presence of ulcers. The distress is present when the stomach is empty and is usually relieved by food and antacid. Symptoms of activity may last from several weeks to several months, followed by prolonged and complete remissions.

Treatment.—In few diseases is it so important to get complete coöperation of the patient through a careful and detailed explanation of the rationale of the management. Most cases can be treated ambulatory with as good results as with complete rest in bed.

Diet.—A graduated diet which begins with milk, cereals, soft-boiled eggs and toast and which is gradually increased by adding more of the bland and less irritating foods forms the basis of the dietary management. The food should be well cooked and given in small amounts. Coarse rough foods, raw vegetables, nuts, mustard, catsup, condiments and highly seasoned foods must be avoided indefinitely. From one to four teaspoons of olive oil given before meals is of value as it helps inhibit gastric secretion. At first feedings principally of milk are given every hour, after about four weeks every two hours, and after two months three principal meals together with milk between meals and at bedtime. A special diet sheet giving foods permissible for a period of about two months should form the basis of ambulatory management.

Medication.—The old Sippy powders given twelve to fourteen times a day are no longer necessary. Many cases fared badly under that management because of either the development of alkalosis or the production of an acid rebound following some of the doses of alkali. Alkaline powders may be given after each of three meals and once or twice in the evening. With the milk at the hour feedings atropine in solution, about 1-125 gr., should be given four times during the day; also Amphojel or Creamalin should be given four or five times during the day in two teaspoon doses. Alutropin, preparations of magnesium trisilicate and Malcogel, may be substituted for the Amphojel. Concentrated vitamins, especially containing large doses of B and C, should be administered because of the restricted diet. If anemia is present iron should be administered. Benzedrine in 10 mgm. doses is very good for spasm. The patient should be under strict management for at least six months and after that under careful observation for at least a year. At first the patient should consult the doctor about once a week. If stomach distress should return at any time the patient should place himself at once on the second or third week diet.

Complications.—Many of the complications are surgical in nature. The most common one is partial or complete obstruction. This may be due to spasm, inflammatory edema or scarring. Careful management with large doses of atropine should relieve the obstruction very promptly if it is not due to scarring. For the latter surgery is indicated. The most characteristic symptom of obstruction is ulcer distress at a time when the stomach should be empty. In severe obstruction there is usually anorexia, epigastric fullness, nausea, vomiting and in thin individuals visible peristalsis. Midnight or early morning distress suggests gastric retention. The x-ray helps to establish the diagnosis. The next important complication is hemorrhage. Massive hemorrhages occur in asymptomatic ulcers in 50 per cent of the cases. The symptoms are weakness, breathlessness, fainting, hematemesis and tarry stools, also a posthemorrhagic anemia. Patients under forty-five years usually respond to medical management; in those over forty-five surgery is often necessary because of the tendency to fatal hemorrhage. The next important complication is perforation. The symptoms may be sudden, agonizing pains in the epigastrium with board-like rigidity. Slow perforations may occur in the posterior wall of the duodenum with pain, localized tenderness, fever and leukocytosis. The treatment is surgical.

Conclusions.—The management of peptic ulcer is medical, but many of the severe complications are surgical. For most cases ambulatory management is very satisfactory. The patient's confidence and coöperation must be obtained by careful explanation of the rationale of the treatment. Hyperacidity nearly always accompanies peptic ulcer. It apparently plays an important part in the production of clinical ulcers. Neutralizing mixtures are replacing the strong alkaline powders formerly used in the treatment of ulcer. In the early phase of this treatment patients should visit their physician frequently. Ulcers with obstructive symptoms should first be given thorough medical management before advising surgery. Surgery should be considered early in cases when massive hemorrhage occurs in patients over forty-five years old. The present-day medical management of uncomplicated duodenal ulcer brings gratifying results. Gastric ulcer because of the accompanying fibrosis and the possibility of superimposition of malignancy is more often surgical.

THE SURGICAL MANAGEMENT OF PEPTIC ULCER—A CHEMICAL PROBLEM

(Abstract)

O. H. WANGENSTEEN, M.D.
Minneapolis, Minnesota

Surgery enjoys an important role in the management of ulcer, only because of ineffective and inadequate control of gastric acidity by conservative means. In other words, the surgical management of ulcer begins

with medical failures. The patient with an ulcer who is being managed satisfactorily by a dietary regimen is not a candidate for surgery. When sure and effective depressants of gastric acidity become available, the role of the surgeon in the management of ulcer will become a less important one than it is now. Surgeons who operate for the relief of ulcer will be the first to make this concession.

The frequency with which ulcer looms as a medical problem in the military forces indicates that the management of ulcer is a very live question. The medical military experience of the English and the Canadians in the present conflict suggests that, next to flat feet, ulcer is the most frequent cause of disability amongst enlisted men. Our own Medical Department is encountering ulcer as a frequent problem in the Armed Forces.

Operative procedures directed at the relief of ulcer which fail to reduce gastric acidity are potentially dangerous and should be abandoned. Only an extensive gastric resection (three-quarter resection) with complete excision of the antral mucosa affords real promise of effectual reduction of gastric acidity, the *sine qua non* of a satisfactory operation for ulcer. This operation can be done as a one-stage procedure in all ulcers (except acute perforation) and with minimal mortality (2 to 3 per cent). This procedure appears to rid the patient for good and all of the ulcer diathesis. As far as is known now, it does not compromise the future for him in any important manner. After the lapse of a few months (three to four) the gastric capacity of these patients becomes quite normal again. During that interval, it is important that the patient eat often. No other dietary strictures are enjoined on the patient. Meat, vegetables and fruit which ulcer patients frequently have been denied, become for months and even longer, the favored object of the gustatory explorations of these patients. Ulcer patients accustomed to a somewhat liberal intake of fat may lose weight after operation. With an eye to maintenance of optimal weights for a given height, patients who are below weight at the time of operation are cautioned that they continue a moderately liberal intake of fat, lest they lose weight. For the overweight patient, the new dietary allowances are particularly welcome.

Sealed occult perforation of a duodenal ulcer, in the experience of this clinic, is the most frequent cause of pyloric obstruction. Usually such obstructions relent on constant intragastric drip feeding of a high protein and carbohydrate fluid mixture (Varco gastric diet No. 2) permitting a one-stage resection.

The frequency with which benign and malignant ulcerative lesions are confused suggests the necessity of more frequent operation for gastric ulcer than has been common practice in the past decade.

The operation is to be done with care and deliberation. The experience of this clinic suggests that long operative procedures on patients well prepared for operation are well withstood. More notice should be taken by the surgeon of the length of the hospital stay and the total recovery period, with less emphasis on the length of time spent by the patient on the operating table. It is high time that the traditional interest of the surgeon in the length of the operation, so important in preanesthetic days, be discontinued. In civil surgery there is no need for haste. The planned procedure in practiced hands affords the greatest promise of success.

The importance of employing short or no loop (jejunal) anastomoses in gastric resection for ulcer is pointed out. Spatial separation of the new gastric outlet from the site of entry of bile and pancreatic juice into the intestine by employment of a long jejunal loop invites stomal ulcer. Another probable effect of the same agency is diminution of absorption of secretin from the duodenal mucosa with decreased secretion of alkaline pancreatic juice with high buffer value containing sodium carbonate. On the thesis of Mellanby's consideration of bile as an additional alimentary stimulus for pancreatic secretions, it is suggested that excision of the gall bladder may prove of some value in combating the acid ulcer diathesis.

There are many things yet to be learned about the ulcer problem. It is becoming increasingly evident, however, that the acid-peptic digestive capacity of the gastric juice is the most important factor in the causation of ulcer. The magnitude of the problem of effective control of gastric acidity is real and frequently cannot be achieved consistently by available conservative means. Only operations which reduce effectively the gastric secretory capacity of the stomach have any place in the surgical management of ulcer.

Discussion

Dr. R. T. La Vake (Minneapolis): I would like to ask Doctor Wangensteen a question. Several years ago I had a patient with preeclamptic toxemia who developed a continuous pain in the epigastrium. This is supposed to be a not uncommon symptom of late toxemia. This has not been my experience, however. Her internist, who had taken care of her from birth, felt sure that it was not a gastric or duodenal ulcer. After three weeks' treatment under hospital regime, labor began spontaneously at the beginning of the thirty-second week of pregnancy. She delivered a live premature infant very easily; but, while taking gas, she suddenly stopped breathing; but was finally resuscitated with artificial respiration, and went back to bed after delivery seemingly in excellent condition. Twenty-four hours later she developed pain and distension of the abdomen. Usual treatment for gas distension following delivery was instituted but to no avail; and she finally died.

Her internist felt that the diagnosis must be mesenteric thrombosis. An autopsy was granted, and general peritonitis from a ruptured duodenal ulcer was found.

When I was an intern at the New York hospital, it so happened that we had many perforating ulcers, and I thought that I would never in my life miss a perforation of an ulcer. Her abdomen was soft, not rigid. Were I to see another like case tomorrow, I would mistake the diagnosis.

Ever since this episode, I have wondered if we have been correct in our interpretation of epigastric pains in late toxemia. May it not be a sign indicating the advisability of x-ray gastro-intestinal studies? Certainly epigastric pain in late toxemia is not more frequently found than gastric and duodenal ulcer in nonpregnant women. Have you had any experience with perforation in pregnancy?

Dr. O. H. Wangensteen: The experience which Doctor La Vake relates is unusual. In the first place, we have been led to believe that an active ulcer during pregnancy is decidedly unusual. As a matter of fact, a search for substances in the urine of pregnant women

which would depress gastric secretion had its origin in the observation that remission from the symptoms of ulcer during pregnancy was frequent. In this connection, it may be of some interest to relate that my colleague, Doctor Lyle J. Hay, who is now abroad with United States General Hospital 26, was able to produce ulcers regularly by the histamine-beeswax method, in pregnant animals of several species. As yet, however, we have been unable to produce ulcers in the fetuses of such pregnant mothers in any species of animals by stimulating the endogenous gastric secretory mechanism by employment of the histamine-beeswax technique. This interesting paradox may suggest that there is no secretion of hydrochloric acid before birth by the stomachs of those species of animals injected. On the contrary, there are reported a few instances of spontaneous *in utero* perforation of gastric or duodenal ulcer in the human fetus.

The absence of abdominal rigidity in Doctor La Vake's patient is unusual. It is possible that the stretch of the abdominal muscles incident to pregnancy precluded the presence of rigidity. Ordinarily, however, pain and tenderness, both owing to the escape of a severe irritant, namely, gastric juice, into the peritoneal cavity, should have been present. Shock is a late phenomenon of perforation. Early after perforation, both pulse and blood pressure are unusually normal. It seems very odd that the usual symptoms of perforation should not have been in evidence. A roentgenogram with the patient in the left decubitus position, or sitting, would have been helpful. These films together with a scout film of the abdomen are often helpful in borderline acute abdominal lesions of any kind.

The meeting adjourned.

E. V. Kenefick, M.D.
Secretary.

Meeting of November 11, 1942

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 11, 1942. The meeting was called to order at 8:10 p.m. by the vice president, Dr. H. B. Zimmermann.

There were forty-two members and one guest present.

Minutes of the October meeting were read and approved.

Dr. L. E. Daugherty read the following Memorial to Dr. Harry Parks Ritchie, a member and Past President of the Academy, who died on September 3, 1942. And a motion was carried that it be spread on the permanent records of the Academy and a copy sent to Dr. Ritchie's family with the condolences of the members of the Academy.

HARRY PARKS RITCHIE

1873-1942

Dr. Harry Parks Ritchie died September 3, 1942.

His father, Dr. Parks Ritchie, came to Saint Paul in 1881. He was one of the leaders in the medical profession and was a charter member of the Minnesota Academy of Medicine and its President in 1889. He was Dean of the University Medical School at a critical time in that institution's history—from 1897 to 1906.

Harry Ritchie attended the public schools in St. Paul and went to Yale where he was graduated in 1893. He then attended the University of Minnesota Medical School and received his degree in Medicine in 1896. He taught physiological chemistry under Dr. Beard. His internship was served at the Ancker Hospital with Dr. Warren Dennis, Dr. Walter Ramsey, and Dr. Frank Warren. Shortly after serving his internship, he joined the 13th Minnesota Regiment and was in the Philippines during the Spanish American War. He was a Captain in the Medical Corps.

After the war he joined Dr. Archibald MacLaren and Dr. DeWitt and, after Dr. DeWitt's retirement, he remained with Dr. MacLaren and was associated with him for many years.

Because of his father, his whole life was spent in an atmosphere of medicine and his close association with such men as Drs. C. A. Wheaton, John Rogers, Robert Wheaton, John Rothrock, James Moore, Alexander Stone and MacLaren, and other leaders of that time, his opportunity was great and he made the most of it.

For many years Dr. Ritchie was Associate Professor of Surgery at the University and served that institution well and faithfully. While teaching at the University he became interested in plastic surgery and later in the repair of cleft palate and harelip. His work in this specialty was nationally known.

Dr. Ritchie read his Inaugural thesis at a meeting of the Minnesota Academy of Medicine on February 4, 1903. His subject was "Vaginal Section and Drainage for Suppuration in the Pelvis." He was elected Secretary of the Academy in 1920 and became its President in 1924.

It was my privilege to be associated with Dr. Ritchie for many years and his outstanding excellent characteristics are too many to mention. I do recall that I never heard him speak disparagingly of any one and this was particularly true of the medical profession. His love of children was sincere and great and I believe that the happiest days of his professional career were those spent in correcting their deformities.

His sons, Dr. Wallace Ritchie and Edwin Ritchie, are now with the armed forces of the United States Army.

L. E. Daugherty, M.D.

MALIGNANT MELANOMAS OF THE UVEA AND THEIR PROGNOSIS

FRANK E. BURCH, M.D.
Saint Paul, Minnesota

The great preponderance of all intraocular tumors encountered in ophthalmic practice falls under the group of malignant melanomas of the uveal tract. They have been previously spoken of as sarcomas of the choroid. All are primary growths, about 80 per cent involving the choroid proper, about 16 per cent involving the ciliary body and choroid, and the balance originating in the iris itself. Metastatic sarcomas of the choroid are extremely rare. Gliomas are found only in childhood, are usually congenital, attaining growth as the eye grows from a 16 mm. to a 24 mm. length during the first eight years of life. Practically the only other intraocular tumor met with and then only rarely is a metastatic carcinoma from cancer of the breast, lungs, uterus, or elsewhere.

The incidence of sarcomas is approximately one in three thousand eye cases. The symptoms of beginning melanoma begin with impairment of vision if the posterior pole is involved or a scotoma in the field of vision corresponding to the site of the growth. The scotomas are usually enhanced by the development of retinal detachment in due time and one of the first considerations in study of retinal detachments is the exclusion of an underlying primary growth. As the melanoma increases in size, necessarily it encroaches upon the vitreous chamber or directly causes obstruction to circulation of intraocular fluids and induces glaucoma. If a glaucoma becomes intense it, in turn, may make the diagnosis of melanoma difficult. Thus it will be readily understood why, in cases of retina and fulminating glaucoma, one must ever bear in mind the possibility of an intraocular growth.

Doctor Camp and the author have endeavored to analyze all the histories of melanoma patients encountered at the University Hospital or in private practice, together with all the specimens submitted to our University Eye Laboratory for diagnosis. We have collected 113 histories and enucleated eyes. This analysis has had as its objectives: first, determination of the prognosis, not only in regard to melanomas in general, but also the prognosis according to the type of melanoma. As Dr. Camp will show you, there are five distinct types of intraocular malignant melanoma with variable prognosis dependent upon the type. A pure spindle-cell type affords a very excellent prognosis; on the other hand, the epithelioid type, the fascicular type and the mixed cell group are by no means so favorable as regards prospect for longevity. Our second objective in this research has been to determine the influence of irradiation upon the cytology and indirectly upon metastasis and prognosis in general. One of our further objectives is to determine the effect upon any migrating tumor cells in the orbit of post-enucleation irradiation. Fifty-three patients received postoperative irradiation. It will require a much longer follow-up of our cases to determine whether or not the insertion of radium in the orbit, or treatment with x-rays after enucleation, affords any insurance against local recurrence or development of metastasis. In any event, our melanoma ledger is now in shape to be continued for another decade or two by our department.

Melanomas of the uveal tract are not like melanomas elsewhere in the body. The prognosis for malignant melanomas in other parts of the body has never been considered favorable. Broders and McCarthy traced only four patients with five-year cures in seventy patients. Bloodgood reported only one five-year cure in over 200 malignant melanomas operated by him. In contrast to this, malignant melanomas of the uveal tract enjoy a relatively favorable prognosis. Pahwa, in a recent analysis of 100 cases seen prior to 1935, found that fifty-one were alive after five years. However, no age is exempt from metastasis or recurrence. In a case of Dr. Anderson Hilding's of Duluth, metastasis in the chest and recurrence in the orbit developed sixteen years after enucleation. If we could make biopsies before enucleation, we might be able to determine the prognosis from type and fiber content with some fair degree of accuracy.

In our series of 113 cases, all but 94 were over forty years of age. Another factor influencing prognosis is the fact that many of these patients come when the tumor growth has already attained relatively large size, indicating a growth of many months. Frequently the history reveals that there has been impairment of vision over a period of one or two years. In thirty-five instances glaucoma is recorded. Sometimes the diagnosis is not made until the eyeball is sectioned following enucleation of an intensely painful, blind glaucomatous eye. So that doubtless, in nearly every case, there has been plenty of time for metastasis to develop before a diagnosis of melanoma is made, or enucleation is done.

Even in some very small tumors we have found tumor cells within the lumen of vessels or extensions along emissary vessels and nerves. In five instances penetration through the sclera was noted. Altogether such microscopic extensions or macroscopic penetrations of the sclera are recorded in twenty-two of our series. Twice an undiagnosed melanoma was found on section of phthisical bulbs. With all these local extensions and penetrations of the sclera, it is noteworthy that actual recurrence in the orbit has developed in only six instances. It would seem obvious, therefore, that nature must provide some systemic resistance, or that tumor cells atrophy or undergo necrosis, or that some phagocytic or chemical destruction occurs locally as a means of preventing metastasis and local recurrence. Since acute or absolute glaucoma was recorded in over one-third of our series, which is indicative of an advanced stage of growth, one would expect such cases to be more likely to develop metastasis, or at least local recurrence; but, such is not the case. In only one of these glaucomas, many of which also showed evidences of tumor cell migration, has a secondary orbital growth developed to date, whether radium was inserted or otherwise, and in only eleven of the thirty-nine instances recorded has metastasis developed elsewhere.

It is conceded that all malignant melanomas are radioresistant, or at least not radio sensitive. No attempt has been made to cure malignant uveal melanoma by irradiation. No evidence has ever been accumulated in ophthalmic literature to condemn prophylactic radiation therapy as a means of prevention of metastasis from intraocular malignant melanoma. McKee, Wood, and others have condemned its use as not only valueless but as actually harmful; that melanotic tumors are aggravated and metastasis favored by this line of therapy. R. Foster Moore and H. C. Stallard made attempts to treat melanoma of the choroid by implants of radium and radium sewed to the sclera over the tumor. We have attempted this in two cases and noted a shrinkage in the globe. Stallard concluded, "There is no doubt that for a time the neoplasm becomes more translucent and small. It is probable that some of the sarcoma cells are destroyed, and that these tumor cells treated by phagocytes are eventually absorbed by the blood vessels." Some twenty years ago we conceived the idea that by preliminary irradiation of intraocular malignant melanomas it might be possible to "sterilize" the growth,

so to speak, and then, by waiting until the full effect of irradiation was achieved, to enucleate the eye. Since most cases were seen when the growth was well developed, and opportunity for metastasis had probably existed for some months, we believed that a delay of four weeks, or thereabouts, until the full effects of irradiation were attained could probably afford only slight further opportunity for metastasis. Some cases were seen in which excellent vision was still maintained at the time of diagnosis. In others, the patient could not be reconciled to enucleation when the diagnosis and the prognosis was explained. In one notable case in which malignancy developed from a benign melanoma of the choroid observed by us over a period of thirteen years, the affected eye was the patient's only useful eye. Such cases as mentioned seemed favorable for prophylactic radiation therapy—if any cases were favorable.

In consultation with roentgentherapists, and we are especially grateful to Professor Stenstrom for his help in the matter, a fairly standard irradiation procedure was carried out at the University. A total dosage of 1500 roentgens, as measured by air, was employed in divided doses over a period of fifteen days. For the anterior field a 4 x 5 cm. and for the bilateral field a 4 x 6 cm. field was cross-fired in a series of thirty-five patients. In the main, a 200 kilovolt, 60 cm. target skin distance with a half millimeter copper filter for the anterior field and a one millimeter copper filter for the lateral field, was used. One millimeter of aluminum was always used as a secondary filter. Whenever possible the eye was not enucleated until one month after irradiation. Thirty-five cases were radiated, in most instances according to the above formula. Our study of the follow-ups and, more particularly, study of the effect upon cell structure by Doctor Camp, has failed to prove the value of radiation therapy in the treatment of intraocular malignant melanomas. Moreover, the results would seem to indicate that no one of the five cell types has responded to this form of therapy very favorably. This analysis, of course, does not include a very large series, but to us it has been sufficiently convincing. Perhaps over a long period of time follow-up data may alter our statistics slightly. That the dosage has been sufficient seems probable, because there have been several cases followed by contraction of orbital tissue—in a few, actual radium burns. Any effective radiation dosage (we must conclude) which *might* destroy tumor cells would damage healthy, adjacent tissues and the resistance which they naturally afford. If local adjacent cell resistance is damaged by an overdosage of x-rays or gamma rays, especially if local blood supply is impaired by their use, one might expect an unfavorable sequence.

Doctor Camp will enlarge upon this subject but, from our experience with prophylactic radium therapy for the purpose of arresting growth, preventing metastasis, and improving the prognosis, the conclusion is now very definite that this form of therapy is valueless. Whether or not irradiation immediately after enucleation, given for the purpose of preventing local recurrence or extension of tumor cells into the circulation accomplishes any purpose, will require longer observation of the series in which it has been employed in order to determine the facts. As a result of our experience in this small group of cases, however, we must conclude that:

1. Even with intensive irradiation its action is uncertain in all types of malignant melanoma.
2. Roentgen therapy offers no assurance against metastasis; there is a bare possibility, when complete figures are available covering a longer period, that metastasis develops earlier after prophylactic use of irradiation than when it is not so employed.
3. Irradiation should be reserved for cases in which the tumor-containing eye is the only one retaining vision, for cases where the patient refuses enucleation, and those in which the tumor has already invaded the orbit and adjacent structures.
4. Early diagnosis and immediate enucleation remain of greatest value in prognosis.

PROGNOSIS OF MALIGNANT MELANOMATA OF THE UVEA FROM THE STANDPOINT OF PATHOGENESIS, CYTOLOGY AND FIBER CONTENT

WALTER E. CAMP, M.D.
Minneapolis, Minnesota

Probably no other group of tumors has given rise to as much controversy and argument in the matter of histogenesis or pathogenesis as has malignant melanomata of the eye. Since these tumors were first described as melanoses by Laennec in 1819, they have variously been classified as sarcomata (leuko-sarcomata and melano-sarcomata); endotheliomata; peritheliomata; chromatophoromata; melanoepitheliomata; and lastly, neuroblastomata or neuronevus, or tumors of neurogenic origin.

Our present concept is that these tumors of the uvea belong to a larger group of similar tumors, all of neurogenic origin. The origin of this class of tumors from the cells of the sheath of Schwann of the nerves, or of the nerve end organs was first shown by the work of Verocay (1910); by Harrison (1924) and Masson (1926-32); Laidlaw and Murray (1933); and lastly by Theobold (1937), the latter applying the findings of the previous writers to the eye, particularly the uvea.

Now that the problem of pathogenesis has been fairly well established, the pathologists have in recent years concerned themselves chiefly with a study of the prognosis of these growths.

In addition to the general rules of malignancy laid down by pathologists for all tumors, probably the most contributory studies on the prognosis of malignant melanomas of the uvea have been made by the cytological studies of Callender and the "fiber content" studies of Callender and Wilder.

Callender, in 1931, reported on 111 cases of malignant melanomas of the eye and classified them into

five groups on the basis of cell types and arrangement of cells.

The spindle cell is the most frequent of all cell types, forming the entire mass of some tumors and part of the so-called mixed cell type and fascicular type. It may be subdivided into:

I. *Spindle Cell A*
Spindle cells small, densely packed and seldom show a well-defined nucleolus—Tumor usually heavily pigmented.

II. *Spindle Cell B*
Larger spindle cells—fairly large chromatic nucleus with well-defined nucleolus—pigment moderate or slight in amount. These cells always are a component of the so-called mixed cell type and fascicular type to be described below.

III. *Epithelioid Type*
Large rounded or polygonal cells with chromatic nucleus and large nucleolus Many cells multinucleated and occasionally quite large. Pigment usually moderate or slight. This type of cell is also found in the mixed cell type.

IV. *Fascicular Type*
Spindle shaped cells with a large nucleolus resembling Spindle B above and with occasionally rounded or polygonal forms. Cells arranged in columns or fasciculi—the long axis of the cell being at right angles to the column. The cells are arranged around a lymphatic or a blood vessel. Pigment is usually scanty, but occasionally may be abundant. This cell arrangement may also be found in the mixed cell type.

V. *Mixed Cell Type*
Usually most common type of cellular structure in malignant melanoma of the eye. A mixture of spindle cells and epithelioid cells with areas of fascicular arrangement. Some areas of tumor deeply pigmented; others devoid of pigment.

From an analysis of Callender's cases, he shows that the epithelioid type is most malignant; fascicular type next; then mixed; and lastly Spindle B and Spindle A.

If the prognosis of these cases of malignant melanomas of the uvea is compared to other cancers, i.e., a five-year cure, it will be seen that in class Spindle A, two of the eleven cases followed were dead in five years; in Spindle B, none of twenty cases that were followed; in the fascicular type, two of six cases (33⅓ per cent); in the epithelioid type, four of ten cases (40 per cent); in the mixed cell type, eighteen of fifty-five (32 per cent) of the cases followed.

At the University Hospital laboratory, we have studied ninety-seven cases of malignant melanoma of the uvea contributed from the Miller Hospital, University Hospital, and private physicians, who were kind enough to send in specimens for study. We have complete "follow-ups" on ninety of these cases.

They have been classified and studied similar to those of Callender, and we have the following results after a six-year period:

Classification	No. Dead	No. Cases	Per Cent
I Spindle A	1	8	12
II Spindle B	6	29	20
III Epithelioid	11	22	50
IV Fascicular	6	9	66
V Mixed Cell Type	7	29	25

As a further aid to prognosis, Callender and Wilder, with a modification of Foot's stain, were able to impregnate these tumors with silver salts to show an argyrophil reticulum. In a study of two hundred and five tumors, so stained, they classified them into three large groups depending upon their fiber content.

Group 1. Those having no fibers or fibers only in the interlobar stroma.
Group 2. Those having areas with and without fibers (combination of 1 and 3). This group subdivided into:
(a) Tumors having a preponderance of fiberless areas.
(b) Tumors having areas with and without fibers approximately equal.
(c) Tumors having a definite preponderance of areas containing fibers.
Group 3. Tumors having fibers among the tumor cells throughout all areas.

In their group of two hundred and five cases studied, they have followed forty-six for a period of five years or more. The mortality of the various fiber groups are shown in the following table:

Class 1	100 per cent deaths
Class 2a	87 per cent deaths
Class 2b	76 per cent deaths
Class 2c	22 per cent deaths
Class 3	0 per cent deaths

In our series of ninety-seven cases, we have fiber stains, on twenty-nine cases that have been followed for a period of six years or more, and find the following mortality in six years in the various fiber groups:

Classification	No. Cases	No. Dead	Per Cent
Fiber Group 1	0	0	0
Fiber Group 2a	8	5	61
Fiber Group 2b	15	2	13
Fiber Group 2c	6	1	17
Fiber Group 3	None		

In comparing the various fiber groups with the cell type groups, it is found that of the total of eight dead, of twenty-nine cases after six years—two were Spindle B, one fascicular, three epithelioid, and two mixed cell types.

The greatest variation of our mortality in the various groups from that of Callender and Wilder is found in Group 2b, where we have only 13 per cent and they have 76 per cent. A larger series of cases would probably give more uniform results.

Discussion on Papers by Doctor Burch and Doctor Camp

Dr. H. B. Zimmermann, Saint Paul: I was much interested in the papers of Doctors Burch and Camp, especially their observations of the varying degree of malignancy observed in these tumors. More and more abdominal surgeons, by using silver impregnation techniques, have demonstrated that nerve sheath tumors are not at all uncommon in the abdomen and retroperitoneal space. As I understand Doctor Camp, he feels that he is able, in a measure, to determine the malignancy of Schwann sheath tumors of the eye by the richness of the collagen fibers as demonstrated by the silver impregnation stain. I do not recall that this observation has ever been made on intra-abdominal Schwann sheath tumors. If there are any pathologists present tonight, I wish they would discuss this point.

Dr. Arnold Schwyzer, Saint Paul: One cannot help being greatly surprised at the large number of cures Doctor Burch has had in melanomatous tumors. That is very different from what we see in general surgery. A man like Doctor Bloodgood of Johns Hopkins, with the large material there, had seen only one five-year cure. It must be we have some special conditions. Many may not be as malignant as in the rest of the body. One sees them early in the eye when they are still small; while the surgeon usually gets them when they are already of pretty good size.

When I saw the program, I hunted for the notes of a case I thought might be of general interest and also looked up the microscopic sections. The tumor cells had the appearance of epithelial tissue with large nuclei with little cytoplasm and no intracellular substance to be made out nor any cell membranes, only here and there a little connective tissue. The picture resembled mostly what Doctor Camp in his wonderful demonstration had shown as Class 4 of his cases. There was some pigment here and there, and macroscopically the growths were moderately melanotic.

The woman I speak of above, came to me in October, 1937, with a lump on her right arm. She had a little pain in it but said she knew that it was nothing serious. Her doctor had told her it was simply a fatty tumor. Then she had gone to a clinic a short while before I saw her. A biopsy had been done, and she had the report that it was benign. The tumor was the size of a small plum. It seemed like it was attached to the deltoid fascia underneath. I told the patient it was serious and excised the mass with much healthy fat surrounding it and also took along the fascia of the deltoid underneath.

Large doses of radium and x-ray were then given, and she stayed well until December, 1938, when she had an abscess in the midline above the promontory due to appendicitis. The appendix was removed and the patient recovered, but in February, 1939, she returned to the hospital with a hemoglobin of only 35 per cent and the stools black with blood. After massive transfusions, an x-ray showed she had a tumor in the stomach the size of a hen's egg rather far up on the greater curvature and posterior wall. The stomach was resected, and she then felt well until the summer of 1939 when the hemoglobin had again come down, and in August and October she received blood by transfusions. In October, on return from my vacation, I found a large mass in the mid abdomen and the stools again contained much blood. We had to resect about 18 inches of ileum together with the mesentery into which the growth had progressed. Again, it was a slightly melanotic, soft growth, the same in character as the growth on the arm and of the stomach. She felt well then for two years, but in October, 1941, was attacked by a sudden intestinal obstruction. Two loops of ileum were grown firmly together and through the slit in the mesentery another loop had become strangulated. These adhesions were undoubtedly remnants of her appendiceal abscess. Last spring she made us aware of a small tumor above the left knee which was excised and proved to be a simple fat necrosis—perhaps from a hypodermic. About two weeks ago she came to the office asking for some medicine because she did not want to grow too fat.

Dr. Frank E. Burch, in closing: I am grateful to Doctor Schwyzer for giving us the general surgeon's experience as it relates to our subject. In considering prognosis, I wish some one could tell us what happens to these tumor cells when they wait ten or twelve years before they start secondary growth somewhere else; how they remain dormant; and why metastases develop so uniformly in the liver. Doctor Newton, of Dallas, Texas, in 1938 reported a case where a local recurrence came after twelve years, but without evidence of metastasis elsewhere. However, when I saw him recently and asked him about it, he said the patient died of metastasis in the liver a year later. He had a recurrence in the orbit after twelve years and after fifteen years developed metastasis of the liver.

I would like to compliment Doctor Camp for the tremendous amount of work he has done in classifying these tumors and for the painstaking work he has done in examination of sections to find out the influence of "fiber content" on malignancy and its relation to prognosis.

Dr. Walter E. Camp, in closing: I want to compliment Doctor Burch for his untiring efforts in following up these cases; there has been a great deal of work to it. I also want to compliment Mr. Morris on his fine color photography of these slides.

Dr. Arnold Schwyzer, of Saint Paul, read a paper on "White Bile." This will be published in full, separately.

The meeting adjourned.

E. V. Kenefick, M.D.
Secretary.

In Memoriam

HIRAM J. LLOYD

Dr. Hiram J. Lloyd, a well known citizen of Mankato and a member of the Mankato Clinic, died December 14, 1942, following a period of ill health for nearly two years.

Hiram Lloyd was born on December 31, 1876, near Judson in Butternut township. He taught school for a number of years before studying medicine at the Chicago College of Medicine and Surgery where he received his medical degree in 1910. After serving an internship in Chicago for a year he began the practice of medicine at Lake Crystal in 1911. Five years later he opened an office in Mankato where he practiced continuously except for a period of service in the army medical corps in 1917 and 1918. After a year overseas he returned to Mankato.

Before studying medicine Dr. Lloyd was in charge of music at the Moody Institute in Chicago. He was endowed with a fine tenor voice and conducted a number of musical organizations in Mankato. Among these were the Mankato Orpheus Club, the Ladies Glee Club and the choir of the Welsh Presbyterian church. He also sang in the choir of the First Presbyterian church for about fifteen years.

One of the outstanding musical events of the community was the oratorio "Elijah" presented in 1927. On other occasions "Creation" and "The Messiah" were rendered under his direction.

Dr. Lloyd was a member of the American Legion, the Disabled War Veterans, Veterans of Foreign Wars, the Masonic Lodge, Knights Templar, Kiwanis Club and was a member of the Blue Earth Medical Society, the Minnesota State and American Medical Associations. He was a member of the Welsh Presbyterian church where in 1935 he organized the present church choir and directed it for a number of years.

On November 9, 1904, he married Margaret Jones and last year their anniversary was celebrated at St. Joseph's Hospital, where he was a patient, with a reception for his many friends.

Dr. Lloyd is survived by his wife; two sisters, Mrs. Margaret Lloyd Davies, Mankato; Mrs. John B. Jones, Lake Crystal; and two brothers, John Reese Lloyd, Palo Alto, California; and Elias Loyd, Monticello, Florida.

OLE SAMUEL SWENNES

Dr. O. S. Swennes of Wahkon, Minnesota, died suddenly of a heart attack December 20, 1942, at the age of seventy-five.

Dr. Swennes was born March 12, 1867, in Barre Mills, Wisconsin. He received his Bachelor of Arts degree from Luther College in Decorah, Iowa, in 1891. His medical degree was obtained at Rush Medical College in Chicago in 1894. After practicing at Northfield and Milaca, in 1898 he moved to Wahkon.

In 1904 Dr. Swennes was married to Severa M. John-

There Is NO Essential DIFFERENCE Between RED LABEL and BLUE LABEL KARO

These two types of KARO differ only in flavor. In chemical composition they are practically identical. Their caloric values are the same.

If your patients find grocers temporarily out of one type, the same amount of the other may be prescribed.

How much KARO for Infant Formulas?

The amount of KARO prescribed is 6 to 8% of the total quantity of milk used in the formula—one ounce of KARO in the newborn's formula is gradually increased to two ounces at six months.

ANNOUNCES CONTINUOUS COURSES

SURGERY—Two Weeks' Intensive Course in Surgical Technique starting February 8 and 22, March 8 and 22, and every two weeks throughout the year.

MEDICINE—One-month Course in Electrocardiography and Heart Disease starting the first of every month, except August.

FRACTURES AND TRAUMATIC SURGERY—Formal and Informal Courses.

GYNECOLOGY—Two Weeks' Intensive Course starting April 5; Clinical and Diagnostic Courses.

OBSTETRICS—Two Weeks' Intensive Course starting April 19; Informal Course.

OPHTHALMOLOGY—Two Weeks' Intensive Course starting April 5.

OTOLARYNGOLOGY—Two Weeks' Intensive Course starting April 19.

ROENTGENOLOGY—Courses in X-ray Interpretation, Fluoroscopy, Deep X-ray Therapy every week.

UROLOGY—Two Weeks' Course and One-month Course available every two weeks.

CYSTOSCOPY—Ten-day Practical Course every two weeks.

General, Intensive and Special Courses in All Branches of Medicine, Surgery and the Specialties.

February 13—Rheumatic Fever—Diagnosis
February 20—Rheumatic Fever—Treatment
February 27—Focal Infections

E. STARR JUDD LECTURE

Dr. Alfred Blalock of Baltimore, Maryland, Professor and Director of the Department of Surgery at the Johns Hopkins Hospital, will give the tenth E. Starr Judd lecture at the University of Minnesota in the Museum of Natural History Auditorium on Thursday, March 11, 1943, at 8:15 p.m. The subject of Dr. Blalock's lecture is "Traumatic Shock with Particular Reference to War Injuries."

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club, Saint Paul, Tuesday evening, January 12, 1943, following dinner.

The program for the evening consisted of a paper by Dr. Walter P. Gardner of Anoka entitled "Pulmonary Tuberculosis at the Anoka, Minnesota, State Hospital, 1934-1941."

Officers elected for the coming year are: President, Alfred W. Adson, M.D., Anoka; vice president, Walter P. Gardner, M.D., Anoka; secretary-treasurer, Royal C. Gray, M.D., Minneapolis.

WINONA COUNTY MEDICAL SOCIETY

Dentists of Winona County were guests of members of the Winona County Medical Society at the annual meeting held in Winona, Monday evening, January 4, 1943, when Dr. E. D. Risser presented a paper on "Blood Banks and Blood Transfusions," covering special studies he recently completed in an extension course at the University of Minnesota.

Officers elected for the coming year included: President, E. D. Risser, M.D.; vice president, Victor Bruder, M.D.; secretary, A. E. Meinert, M.D.; treasurer, R. H.

Of General Interest

Dr. Paul B. Monroe, formerly of Two Harbors, has established his practice at Cloquet, where he has joined the staff of the Raiter Hospital.

The Foundation Prize of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons consisting of $150.00 is open to interns, residents or graduate students in obstetrics, gynecology or abdominal surgery and to physicians practicing or teaching this specialty. Manuscripts are limited to 5,000 words and should be submitted by June 1, 1943, to Dr. James R. Bloss, secretary, 418 Eleventh Street, Huntington, West Virginia.

SOLAREUM
PAPER TABLE SHEETING

The Modern, Economical Way
For Progressive Physicians

Ready at the head of your examining table is a continuous, instant supply of SOLAREUM sheeting. Here, in a sanitary holder that is especially designed to fit any style of table you might have in your office, you have about 700 to 1,000 lineal feet available, quick as a flash, whenever you need it.

SOLAREUM sheeting is purposely made for efficient service in the modern physician's office. It is conveniently, quickly spread over your table, and is pleasant to lie on. There is no crackling noise, no cold feeling, no discomfort to disturb the nervous patient.

SOLAREUM sheeting is inexpensive, saving nearly all or much of the laundry cost, according to the nature of your practice. It gives you a clean sheet for each patient at minimum cost. Distributed over an entire year this saving is well worth considering.

BROWN & DAY, INC.
Saint Paul, Minnesota

Dr. R. V. Williams of Rushford retired from practice the latter part of December and announced that his associate, Dr. I. Grant Davis, will continue the practice of medicine in the community. Dr. Davis recently completed a special course in refraction at the Illinois Eye and Ear Infirmary at the University of Illinois and will take care of the refraction work formerly done by Dr. Williams.

* * *

Dr. Ernest M. Hammes, chairman of the Medical Testimony Committee of the Minnesota State Medical Association, addressed the joint meeting of the Congress on Industrial Health and the Congress on Legislation of the American Medical Association at their meeting in Chicago, January 11 to 13, 1943, on the subject of the Control of Medical Testimony—The Minnesota Plan.

* * *

During the current quarter 140 medical and dental officers of the Army, Navy, Public Health Service and the Air Forces are assigned through the Surgeon Generals' offices and the various Service Commands for training under the auspices of the Mayo Foundation for Medical Education and Research. The fields in which such training is offered are anesthesiology, aviation medicine, general surgery and surgical specialties, internal medicine and medical specialties, maxillofacial surgery, neurologic surgery, physical medicine, roentgenology and thoracic surgery. Officers are assigned for periods of training varying from six to twelve weeks.

* * *

A portable orthopedic fracture bed will be purchased with funds to be raised through the efforts of the Wells Junior Chamber of Commerce, according to an announcement made last December. The bed will be available for use of residents in the following towns and surrounding communities: Wells, Brycelin, Delavan, Easton, Frost, Kiester, Walters, Conger, Mansfield, Manchester, Armstrong, Alden, Hartland, Freeborn, Minnesota Lake, Mapleton, Waldorf, Matawan, and New Richland. The bed will be readily available to any physician in the listed areas, should an emergency arise.

* * *

Creation of an additional home for the feebleminded "at the earliest possible moment," due to the tremendous waiting list of patients badly in need of removal from their present surroundings, was recommended by Dr. D. E. McBroom, director of the mental health unit of the division of public institutions, in his report to Carl H. Swanson, public institutions director, who submitted his biennial report to Gov. Harold E. Stassen and the state legislature in January.

"The feebleminded problem is perhaps the biggest individual problem the state has to meet as we have a long waiting list and so many patients are creating a situation so bad they should be removed from their surroundings at once," Dr. McBroom urged.

Hospital News

Dr. George E. Penn was elected president of the staff of the Immanuel Hospital, Mankato, at the meeting of staff physicians in January. Other officers chosen at the meeting were Dr. A. F. Kemp, vice president, and Dr. J. A. Butzer, secretary-treasurer.

* * *

Dr. P. G. Boman is the new chief of staff of the Miller Memorial Hospital at Duluth. He succeeds Dr. Carl O. Kohlbry. Other officers are Dr. E. L. Armstrong, vice chief of staff; and Dr. E. E. Barrett, secretary-treasurer. Dr. Kohlbry and Dr. W. J. Ryan were named to the Executive Committee.

* * *

Dr. Jean J. Darius of Lame Deer, Montana, began his duties as senior physician at the Indian Hospital in Bemidji, late in December. He succeeds Dr. James Klock, who recently resigned to take up duties elsewhere.

* * *

St. Mary's Hospital, Detroit Lakes, was recently the recipient of an oxygen therapy machine donated by the American Legion of Detroit Lakes.

* * *

Mrs. Alma Grothe is the new superintendent at St. Francis Hospital, Hastings, succeeding Mrs. Wallace H. Erickson, resigned. Mrs. Grothe is a graduate of St. Luke's Hospital, Fargo, North Dakota. Prior to taking the position at St. Luke's Hospital, she was instructress of nurses at Hillcrest, Minneapolis, for three years and superintendent of a hospital in Sioux Falls, South Dakota, for some time.

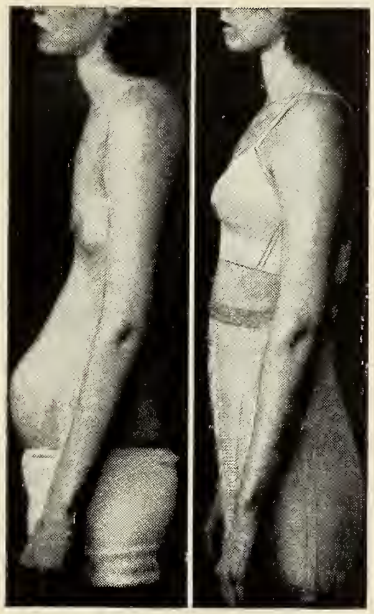
Physicians in Military Service



Dr. Harold S. Diehl, dean of the Medical School, has recently received word of military honors bestowed on three medical officers who are graduates of Minnesota.

The Distinguished Service Medal of the Army was given to Col. James O. Gillespie of the Class of 1925 for work in developing hospitals in Bataan during its siege. Col. Gillespie is now a prisoner in the Philippines.

Captain William W. Moir, Class of 1938, received the Distinguished Service Cross for continuing to direct treatment of his men after he had been wounded when a transport plane in which he was traveling was shot down the morning of Nov. 8. "During the attack in the air and ensuing strafing of the ground, Moir distinguished himself by extraordinary heroism," his citation concluded.

Lieut. John H. Peterson of Duluth, a graduate of the University of Minnesota Medical School in 1932, was awarded a Silver Star medal recently, according to a Navy announcement. Stationed on the destroyer *Hammann* when it was sunk with the aircraft carrier *Yorktown* off the Midway Islands some months ago, Lieutenant Peterson struggled to a lifeboat after the destroyer was sunk and with the help of a torpedoman picked up wounded seamen. Although both were wounded, they made several rescue trips to take wounded men to a nearby destroyer and rendered medical aid to the wounded for three days to the point of exhaustion.

Patients with Long-Standing Ptosis

A B

Are Grateful For Relief Obtained By Individually Designed SPENCER SUPPORT

A: *Patient with extreme case of enteroptosis. Probably has movable kidney, also.*

B: *Same patient in the Spencer that was designed especially for her. Note support given — and improvement in posture.*

A large number of doctors have remarked the immediate favorable reaction of patients with long-standing ptosis to a Spencer Support. This is because the Spencer has been designed especially for patient *after* a study of patient's posture habits has been made. Thus our designers are enabled to create a support that will improve posture.

A Spencer Support gently lifts sagging organs, while allowing freedom at upper abdomen. This, plus posture improvement, aids digestion, elimination and improves circulation of blood through abdomen. Appetite usually improves. The patient's improved posture induces better breathing, a feeling of well-being and a happier outlook.

Every Spencer is individually designed for patient, of non-elastic material. Hence, the support it provides is constant, and the Spencer can be—and IS—guaranteed NEVER to lose its shape. (Spencers have never been made to *stretch to fit;* they have always been *designed to fit.*) Why prescribe a support that soon loses its shape and becomes useless before worn out? Spencers are light, flexible, durable, easily laundered.

For service look in telephone book under "Spencer Corsetiere" or write direct to us.

Dr. W. F. Schamber of New York Mills left for Miami, Florida, in January to report for military duty.

Dr. Conrad Karleen of Tracy, associated with Dr. W. H. Valentine and the Tracy Hospital for the past two years, has received his commission as captain in the medical corps and is now in Springfield, Missouri, where he is stationed at O'Reilly General Hospital, serving in the capacity of surgeon.

Dr. Bernard Karleen of Balaton, a brother of Dr. Conrad Karleen, has entered the Army Medical Air Corps at Miami, Florida.

* * *

News of Minneapolis physicians engaged in war service contains the following items:

Dr. George Bergh has been promoted to the rank of major, according to information received by his parents, Dr. and Mrs. L. N. Bergh of Montevideo. Dr. Bergh is serving with the American Expeditionary Forces overseas.

Captain Henry H. Michel has been ordered to duty with the Army Air Force at Miami Beach, Florida.

First Lieutenant Fabian John McCaffrey is under orders to report to Army Air Force station at Miami Beach early in February.

Lieutenant Commander John F. Pohl has been ordered to report to the National Naval Medical Center, Bethesda, Maryland, February 15.

Lieutenant Commander Lawrence M. Larson who has been commanding officer of the Naval Hospital, Wold Chamberlain Field, is now en route to some undisclosed point in the South Pacific to serve as Flight Surgeon with a Marine aviation unit.

Lieutenant Commander Hugo E. Miller is receiving congratulations on his recent promotion. He has been relieved from duty with recruiting and assigned to the Naval Hospital, Seattle.

Captain William W. Moir, Jr., DSC, son of the late W. W. Moir, has received the Order of the Purple Heart. He was wounded and decorated for gallantry in action in North Africa.

Major Donald W. Pollard has been assigned to administrative work at the Kennedy General Hospital, Memphis. This is a new hospital which is being expanded rapidly.

Major William J. Noonan has been transferred from Fort Leonard Wood to the 126th Station Hospital, Camp Grube, Oklahoma.

Captain Benjamin J. Palen is now taking graduate work in surgery at Harvard Medical School, following which he will return to the Station Hospital, AAF Bombardier School, Big Spring, Texas.

Captain Harold G. Benjamin is reported to have been sent to an overseas theater of war.

Lieutenant Maynard C. Nelson is reported en route to a post in the South Pacific.

Major Reuben Berman has been transferred to the 14th Bomb Wing, stationed at McDill Field, Florida.

INFLUENZA—PNEUMONIA—ENCEPHALITIS
THE STATE BOARD ASKS YOUR AID

Influenza—Two types of influenza are known at present, "A" and "B". The distribution and extent of infection with these two viruses may be determined through your aid.

Pneumonia.—Recently there has been much interest in so-called atypical or virus pneumonias. Very little is known of their etiology. The Division of Preventable Diseases wishes to study these diseases and asks your aid. The Rockefeller Foundation for some years has aided the Division of Preventable Diseases in the study of Influenza and related diseases. But the expense and the time-consuming technique necessary have restricted the studies chiefly to institutional outbreaks.

New serological techniques have been devised that are rapid and inexpensive. Neutralization tests on sera to determine a rise in the antibody content of convalescent serum as compared with serum taken during the first two or three days of illness will establish diagnosis.

Mailing outfits will be supplied, on request, by the Division of Preventable Diseases. The first serum specimen is to be taken on the first two or three days. The sera for comparison of antibody content in suspected influenza ("A" or "B") between the tenth and fourteenth day after onset.

Encephalitis.—In suspected encephalitis of the equine and St. Louis types, the later specimens for comparison of antibody content should be taken two to six weeks after onset, and in lymphocytic choriomeningitis, from the second to the fourth month after onset.

Health officers and physicians in contact with outbreaks of this character and physicians who see suspected cases, will please coöperate.

MENINGITIS MORE FREQUENT

Many more cases of meningococcus meningitis are being reported by state health officers to the U. S. Public Health Service each week than have been reported at this season any time in the last five years.

During the year just ended (1942), there were 3,774 cases reported altogether. This is a larger total yearly figure than any year since 1937, when there were 5,390 cases.

At present, and for some time past, the cases have been confined to the extreme eastern part of the country and the Pacific coast.—*Science News Letter,* January 30, 1943.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

MENTAL ILLNESS: A GUIDE FOR THE FAMILY. Edith M. Stern, with the collaboration of Samuel W. Hamilton, M.D. 134 pages. Price, $1.00, cloth. New York: The Commonwealth Fund, 1942.

THE EYE MANIFESTATIONS OF INTERNAL DISEASES. I. C. Tassman, M.D. 542 pages. Illus. Price, $9.50. St. Louis; C. V. Mosby Co., 1942.

This is the first book of this character since that published by Foster Moore ten years ago. A correlation is made between the eye manifestations and the other medical aspects of the internal diseases by providing a very detailed description of the ocular findings. The first few chapters are devoted to a description of the normal and abnormal structures of the eye, together with a description of the method used in making a complete ocular examination of the patient, and a listing of the general causes of eye manifestations.

The remainder of the book has to do with congenital and hereditary eye manifestations; infections and infectious diseases; tuberculosis; virus infections; fungus infections; ocular parasites and parasitic infections; focal infections; drug and chemical intoxications; diseases of the cardio-vascular system; diseases of the blood; diseases of menstruation and pregnancy; diseases of the endocrine glands and metabolism; avitaminosis and intracranial tumors; diseases of the skin; diseases of bones of the skull.

Obviously, this is a rather complete presentation dealing with systemic lesions. The clinical picture is given first and this is followed by the ocular manifestations. This book, I think, is suitable for the teaching of the student who should be impressed with the relationship of ophthalmologic diseases to general medical conditions.

T. J. EDWARDS, M.D.

THE ANSWER IS—YOUR NERVES. Arnold S. Jackson, M.D. 1942. 200 pages. Price $2.00. Madison, Wisconsin: Jackson Publications.

Individuals who suffer from functional disturbance constitute the greater part of the practice of most physicians. Most of these patients in the stress of modern living and particularly during this period of world strife are beset by worries and fears of various sorts and are lacking in a philosophical attitude toward life and in religious faith. They haven't learned how to live.

For this large group of patients this volume has been written. It contains some medical information which should be of value to the nervous patient in aiding him or her to understand some of the dis-

turbances which account for nervous symptoms and does not ignore the importance of seeking medical advice instead of worrying.

The pages contain much philosophical advice and many hints as to hobbies and outside interests which make life so much more interesting and counteract the causes of "nerves." The chapter by the Reverend Edwin O. Kennedy of Madison on Religion and Nerves stresses the value of faith in a loving God, Bible scripture and church attendance in combating worry and nerves and is a valuable contribution to the volume.

Physicians too often neglect the opportunity to be of greatest assistance to these patients who suffer from just nerves. For this reason the reading of "The Answer IS—Your Nerves" would be of value to physician or surgeon. And the loaning out to patients of one or more copies might well fulfill one of the purposes of the book—to aid the doctor in treating his nervous patients.

C. B. D.

THE BLOOD BANK AND THE TECHNIQUE AND THERAPEUTICS OF TRANSFUSIONS. R. A. Kilduffe and Michael DeBakey. 558 pages. Illus. Price $7.50. St. Louis: C. V. Mosby Co., 1942.

The recent work done in the field of blood transfusion has reached tremendous heights. Of course the present war has stimulated this branch of therapy and the average physician has had difficulty in keeping abreast of the topic. This book should be an answer to his problem. It is concise but still retains a completeness that leaves the reader with a sense of "knowledge security."

The principles of transfusion are adequately discussed and the practical aspects are satisfactorily described. The diagrams and illustrations enable the reader to easily grasp the expressed idea with little effort.

The discussion of shock and its treatment is especially well done by the authors.

The book is not one that can be read hurriedly, because in doing so, much valuable information would be missed.

Joseph M. Ryan, M.D.

THE MIND AND ITS DISORDERS. James N. Brawner, M.D., Medical Superintendent, Brawner's Sanitarium, Smyrna, Ga. Cloth. Price $3.50. Pp. 228. Atlanta, Ga.: Walter W. Brown Publishing Co., 1942.

Dr. Brawner, in the preface to his volume, "The Mind and Its Disorders," states that he is writing primarily for the benefit of the general practitioner, and that his intention is to present the subject clearly, briefly, and in language as simple as the subject permits. To the reviewer, it would seem that he had been too successful in accomplishing this purpose. The work covers a wide variety of neuropsychiatric disorders, too many to be described adequately in the brief space he allots to each condition.

The book is simply written and easily read. The reviewer feels that its style and simplified form may convey to the reader an underestimation of the impor-

tance and extent of care psychiatric cases require. The paragraphs on etiology are over-simplified and are apt to leave the impression that the causes are well defined and understood. The sections on treatment are brief. Symptomatic treatment is suggested in most instances and the basic principles of treatment are briefly outlined, but little actual aid or advice for handling a neuropsychiatric case is given. The book is especially weak as far as suggested technique and principles of psychotherapy are concerned. The paragraphs on symptoms are more complete and the diagnosis and differential diagnosis are adequately handled in most instances.

For a busy general practitioner, and one not particularly interested in statistics and classification, Dr. Brawner has presented his material in what seems to be an understandable and logical manner. At the end of the various sections in the book is a bibliography, which in places is very complete. This greatly increases the value of the book for those interested in pursuing the subject further.

Throughout the entire book, the author freely states his own personal experiences, opinions, and conclusions. Many of his speculations would certainly be open to question and all have not, as yet, been verified by research. He does, however, give due recognition to others who have different ideas on the subject.

Dr. Brawner is to be commended for his able handling of the interrelationship between internal medicine and psychiatry. He brings out this connection logically and clearly through the entire book. The effect of emotions on bodily functions, and vice versa, is briefly outlined, explained and well organized. This particular section, Part I—The Mind as Related to Cerebral Structures and Functions, will give the general practitioner a good basic introduction to the subject and will help to orient him, should he desire to seek more complete discussions on the subject elsewhere.

If the book is considered by the reader as a stepping stone to more complete works on the subject of psychiatry, it is well worth reading. The average physician, however, will find it does not answer his questions nor solve many of the problems that arise in his care of a neuropsychiatric patient. Dr. Brawner's book, because of its simple terms and brevity, could be used to advantage as a reference book for nurses in their preliminary orientation course in psychiatry. Even in this use, it would have to be supplemented by other books which deal with psychiatric nursing technique.

PHILIP K. ARZT.

INDUSTRIAL HEALTH

(Continued from page 204)

placement examination is a device to select only perfect human material to the elimination of all applicants who exhibit any physical defects. Such is, indeed, not the case. If it were, not only would the social loss be great, but the pre-placement examination would lend itself to the perpetration of a cruel and inhuman discrimination.

Correction of Remediable Defects

"There are functions of the pre-placement examination, furthermore, which are in a sense incidental to the main purpose for which it is made. One of these is recognition of remediable defects. It is good practice to acquaint the applicant with these defects and then to urge the immediate correction of certain defects either as a condition of employment or as a condition of acceptance for an insurance program."

Tendency Is to Employ Disabled

"The pre-placement examination is not given for the purpose of rejecting applicants," he emphasized again in conclusion. A few are unemployable because of infectious tuberculous or luetic disease, for instance. But the whole question is one of the man and the specific job he is to do and rejection for one given position does not necessarily mean that a man is unemployable. Aside from this emergency, the tendency of industry is rightly to employ men with disabilities which are not potential hazards to themselves or to fellow workers."

VOCATIONAL HOSPITAL

. . . An integral part of the Miller Vocational High School offers two special features—Patients receive a maximum of personal attention from student practical nurses—All food is prepared under the direction of a qualified dietitian. Patients remain under the care of their own physicians.

When depression accompanies more fundamental pathology

In many patients, depression may occur as an accompaniment of some more fundamental pathology, either organic or psychogenic. In such cases, the physician should bear in mind that, while Benzedrine Sulfate will not affect the underlying condition, its stimulatory effects may help to alleviate the concomitant depression which so often interferes with the management of the case.

Benzedrine Sulfate Tablets

Brand of amphetamine sulfate

Benzedrine Sulfate is primarily useful in depressions characterized by apathy and psychomotor retardation, but is contraindicated in patients manifesting anxiety, hyperexcitability, or restlessness.

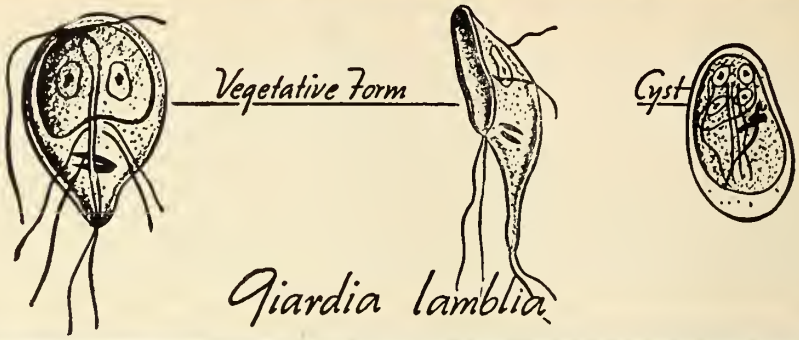
The use of Benzedrine Sulfate by normals should not be permitted; it should always be administered under the careful supervision of a physician; and depressive p ychopathic cases should be institutionalized.

In treating depressed patients with Benzedrine Sulfate, the physician should bear in mind that any drug which produces pleasant or euphoric effects may prove to be habit forming—especially in unstable or neurotic individuals.

SMITH, KLINE & FRENCH LABORATORIES, PHILADELPHIA, PA.

Note to an overworked doctor

BIOLAC is a complete liquid infant formula which saves you valuable time because there are no extra ingredients to calculate.



Biolac provides completely for all nutritional needs of young infants except vitamin C.

Prescribing Biolac reduces the possibility of errors or contamination in formula preparation since it requires simply dilution with boiled water as you direct.

NO LACK IN BIOLAC

Borden's complete infant formula

● *Biolac is prepared from whole milk, skim milk, lactose, Vitamin B_1, concentrate of Vitamins A and D from cod liver oil, and ferric citrate. It is evaporated, homogenized, and* sterilized. *For professional information, write Borden's Prescription Products Division, 350 Madison Avenue, New York City.*

GIARDIASIS

. . . Although evidence for the pathogenic nature of Giardia lamblia is not conclusive, this microorganism may possibly be the cause of diarrhea, abdominal pain and other symptoms of the clinical picture commonly referred to as giardiasis.

It has recently been demonstrated that Giardia lamblia can be eradicated from the intestinal tract with remarkable promptness by the administration of Atabrine Dihydrochloride.

The usual dose of Atabrine Dihydrochloride is 0.1 Gm. three times daily for five days.

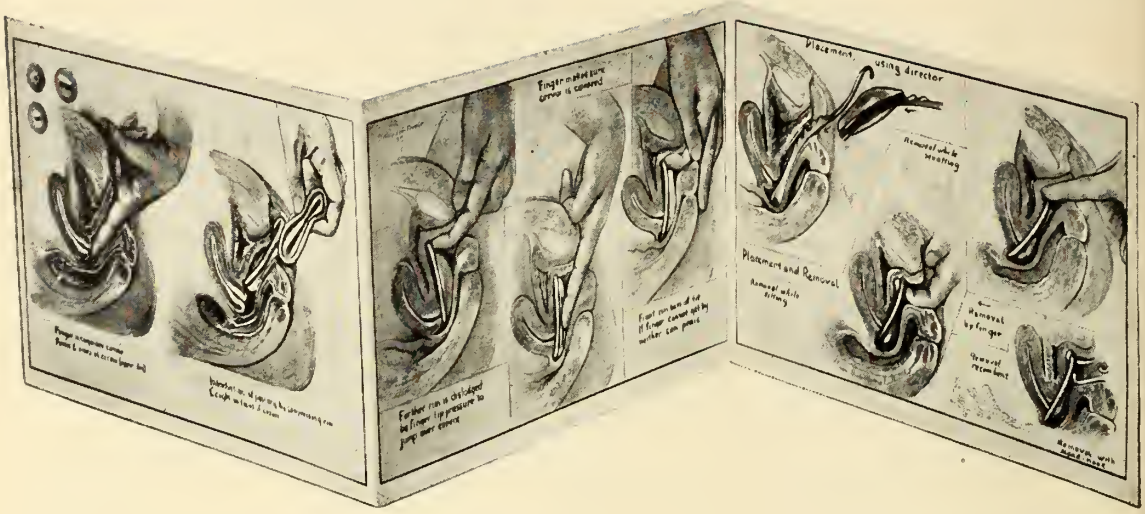
Give the cigarette they prefer to get*

IT'S EASY to understand why cigarettes are the preferred gift in the armed services. But did you know that among them the best-liked brand* of cigarette is Camel? Camel is the popular choice of millions and millions of smokers for its finer flavor and superior mildness.

Send Camels, the service man's favorite, to those friends or relatives who are fighting our battles —fighting them efficiently and unselfishly. Your thoughtfulness will be appreciated.

Tobacco stores feature Camels by the carton. See or telephone your dealer today.

Remember, you can *still* send Camels to Army personnel in the U. S., and to men in the Navy, Marines, or Coast Guard *wherever they are*. The Post Office rule against mailing packages applies only to those sent to the overseas Army.



* With men in the Army, the Navy, the Marine Corps, and the Coast Guard, the favorite cigarette is Camel. (Based on actual sales records in Post Exchanges and Canteens.)

Personalized G-E Field Service Is Not Only For The Duration

● To users of G-E x-ray and electromedical apparatus, the maintenance service rendered by factory-trained men in G-E's local branches and regional service depots is increasingly important these days. And they are getting it despite many of the handicaps which war restrictions impose.

For many years this personalized field service has been available to G-E customers everywhere, who have come to recognize it as a prime requisite to the continued satisfactory operation of all high-grade technical equipment. That's why G-E Field Service functioned before the war and will continue, on a still larger scale, in the peace years to come.

Perhaps you've heard about "P.I. and A"—G-E's *Periodic Inspection and Adjustment Service*—which, incidentally, was not inspired by the exigencies of war, but for thirteen years has helped physicians, hospitals, and clinics to keep their x-ray and electromedical apparatus in tip-top operating condition.

To become better acquainted with these service facilities provided for your immediate vicinity, you need only to get in touch with one of the following G-E headquarters offices or regional service depots. You'll find the G-E representative who calls on you a reliable source of helpful suggestions.

GENERAL ELECTRIC X-RAY CORPORATION

In your particular area this maintenance and technical service is extended through the following G-E offices and regional service depots:

FOR COMPLICATIONS AS OLD AS TIME

IF NEED for stimulation of labor arises in delivery rooms, obstetricians often rely upon Pitocin*, an oxytocic of many advantages and dependable performance.

Pitocin consists of the oxytocic principle of the posterior pituitary gland with practically none of the pressor hormone. Its extremely low protein content so minimizes possibility of systemic reaction that many physicians prefer Pitocin for routine management of obstetric patients.

Pitocin is indicated for stimulation of uterine musculature in uncomplicated obstetrics, increasing tone of the uterus by direct action. It is widely used in uterine inertia during the second stage and to check uterine hemorrhage.

THE DIAGNOSIS OF CORNEAL LESIONS

F. H. HAESSLER, M.D.

Milwaukee, Wisconsin

THE intent of this paper is not to present new facts about corneal disease. All textbooks contain adequate descriptions of the various diseases of the cornea, and once the diagnosis is made, the physician can easily find whatever he may want to know by consulting his books. Unfortunately the patient does not come to the office with a diagnosis pinned to his lapel. Therefore, what I wish to discuss today is how, with the patient before one, a diagnosis is reached, in what order do the signs of corneal disease come to the attention of the physician, how he can evaluate and interpret them, so that the diagnosis will be clear.

Diagnosis is a practical exercise and there are many ways of arriving at it. Rarely does one begin with one observation which can be used as the starting point for a chain of flawless logic. Usually one makes a collection of observations, a mental review of clinical pictures which pass through the mind in less time than it takes to tell and from these one selects several which together may suggest a diagnosis. This is then refined by further differentiation from other somewhat similar disease pictures. An elastic method, rather than the strictly systematic method of, say, chemical analysis, is needed, not only because of the gaps in our knowledge, but because of the nature of the processes we are investigating.

The cornea, on gross inspection, seems to be a homogeneous watch-crystal-like membrane, but it can be the seat of as many distinguishable diseases as any other organ of the body. It may react in a variety of ways to the same type of harmful agent, or, on the other hand, one particular type of reaction may be produced by different stimuli. Thus, at first glance, the diagnosis is rarely clear.

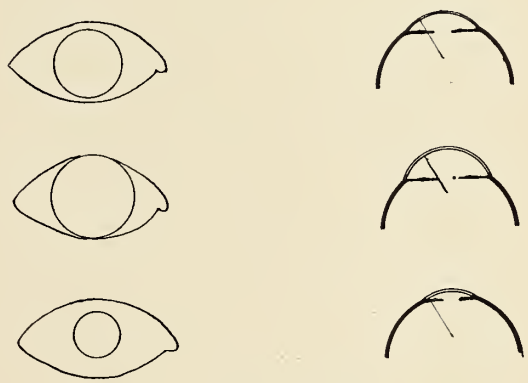

Fig. 1. Diagrams of variants of corneal diameter. From above down: Normal, megalocornea, microcornea. Note that in all diagrams the radius is constant, the diameter variable.

Diagnosis of corneal lesions depends on the observation of the following important manifestations:

1. Changes in size and shape.
2. The presence of pigment.
3. The presence of blood vessels.
4. Modification of transparence.

Sometimes a diagnosis may be made by the analysis of one of these elements. More usually it

Presented in symposium at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

is necessary to recognize a small group of characteristics. Modifications of transparence are so universal in corneal disease that further details of the modification must be described.

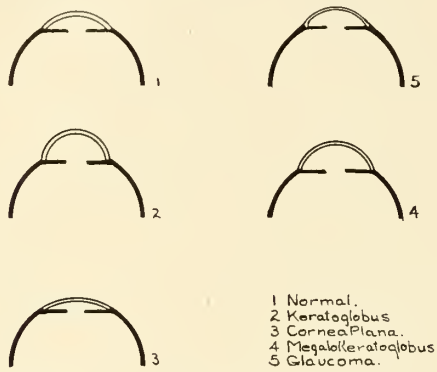

Fig. 2. Diagrams of variants in corneal curvature. In 1, 2, and 3 the diameter is constant and the curvature varies. In diagram 4 there is an increase in both diameter and curvature. Diagram 5 emphasizes an important differential detail which distinguishes megalocornea which is a developmental anomaly from one which is secondary to infantile glaucoma. The sharp line of demarcation between corneal and scleral curvatures is obliterated.

Changes in Size and Shape

The observations of interest are size, curvature and the distance from the iris level. The horizontal corneal radius is 11.6 mm., its radius of curvature 8 mm., and its superficial refraction 45 D. Regular variations from these normal diameters are megalocornea and microcornea, and of the curvatures are keratoglobus and cornea plana. The enlargements—megalocornea and keratoglobus—can only be distinguished by measurement. Most often it is the unusual chamber depth that arrests the attention of the examiner and further analysis is suggested. However, pure keratoglobus is so extremely rare that it need hardly be considered. A matter of real importance is the decision whether the large cornea is a manifestation of gigantism—an anomaly of development—or the result of the fetal or juvenile glaucoma. The latter may have been spontaneously arrested or may still be active. To rule out glaucoma, one searches for the absence of corneal opacities, in particular dehiscences of Descemet's membrane, the normal groove that sharply demarcates the cornea from the sclera, absence of glaucomatous excavation of the optic cup, for normal function, and one measures the tension. In megalocornea, which is a congenital gigantism, bilateral measurements are apt to be identical: the corneal radius is apt to be shorter in gigantism and increased in glaucoma.

When the measurements are appreciably decreased, a diagnosis can usually be made by inspection. Microcornea may be part of a microphthalmos with normal refraction, and distinguishing measurements cannot be made. In cornea plana there is usually no change of curvature at the point of transition from cornea to sclera. For the clinician it is important to remember that 20 per cent of people with microcornea get glaucoma.

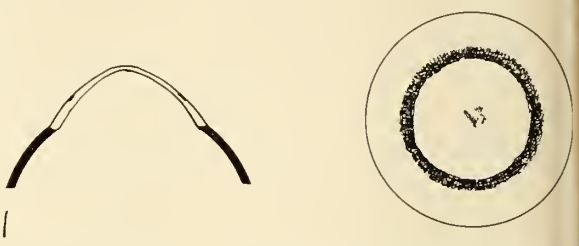

Fig. 3. Diagrams of the characteristics of keratoconus. The figure on the left is a diagrammatic cross section which shows the change in corneal curvature and the location of the pigment ring in the deepest epithelial stratum.
The figure on the right shows the position of the pigment ring and the keratoconus lines and diffuse clouding at the apex.

Keratocornus is also diagnosed by inspection of the globe for variations of size and shape, though in its early stage it is more often suspected from the presence of irregular shadows noted during retinoscopy. It begins near the end of the first decade of life and is characterized by the formation of a cone with a thin apex, keratocornus lines which are parallel wavy lines in the deepest stromal strata, dehiscences in Descemet's membrane, a hemosiderin ring about the base of the cone in the deepest epithelial layers and decreased vision with irregular refraction.

In differential diagnosis congenital anomalies of curvature might be considered, particularly if they are accompanied by rupture of Descemet's membrane. One must not be misled by hyaline infiltration of the corneal apex, which sometimes suggests a cone. The safest diagnostic aids are the cone with thin apex in the optical section of the slit-lamp beam and the hemosiderin ring.

The irregular changes in form, such as facet, Descemetocele, staphyloma, neoplasm, and even pterygium are too obvious and characteristic to need detailed consideration.

Pigmentation

The characteristic pigmentary manifestations are easily recognized if one bears in mind their significant characteristics.

1. Stahli's line: an irregular light brown line,

sometimes branched in the deepest epithelial layers associated with pigmentation of Bowman's membrane.

2. The hemosiderin ring of keratoconus which

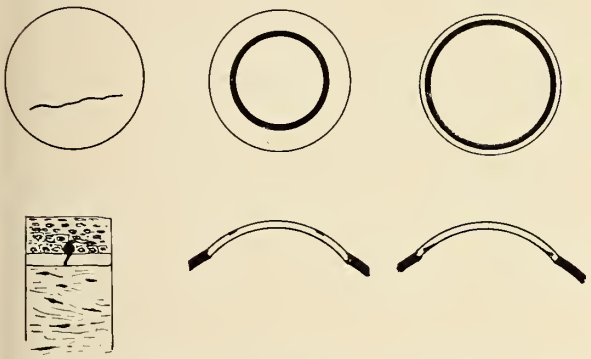

Fig. 4. Pigmentation: 1. Stahli's Line; 2. Hemosiderin ring of keratoconus; 3. Ring of pseudosclerosis and chalcosis.

is in the deepest epithelial layer and surrounds the base of the cone.

3. The Kayser-Fleischer ring, which is a characteristic of pseudosclerosis or Wilson's disease. In this disease, it is always bilateral. It is dark greenish brown, begins at the limbus-like gerontoxon and fades out centrally. It consists of innumerable granules on or near Descemet's membrane. It is also seen in chalcosis and then may be unilateral.

4. Melanotic pigmentation is often seen in the epithelial cells over the limbus and may extend out to the cornea.

5. On the posterior surface uveal pigment may be deposited where the convection current becomes slowed. Some striking forms have received specific names such as Krukenberg's Spindel, but none have specific significance in corneal diagnosis.

As rareties one may observe other colored inclusion in the corneal tissue: (a) blood pigment that has been deposited after laked blood has been absorbed by the stroma after injury, (b) metals, notably silver; and (c) colored crystals such as uric acid in gout.

Corneal Vessels

Vascular proliferation is the most spectacular manifestation of corneal disease. Though there is perhaps no characteristic of blood vessel growth that is pathognomonic of one etiological factor or nosological entity, nevertheless an evaluation of this phenomenon is of utmost importance in diagnosis.

Vessels start as capillary loops and gradually proceed toward the corneal lesion. As the network becomes more extensive some of the vessels become very thick and form a main stem from

Fig. 5. Types of vascular branching. (*Left*) Angle bound vessels of anterior stroma. (*Right*) Level bound vessels of deep stroma.

which smaller vessels get their supply of blood. They may arise from the most superficial network of the limbus and be ultimately conjunctival in origin or they may be offshoots of deeper vessels of the ciliary circulation. Whatever their origin, they arise with great accuracy in the stromal level occupied by the lesion which stimulates their growth. What mechanism may be concerned in producing the proliferation is not completely understood. The presence of pure fibrin alone, a constituent of most inflammatory exudates, is known to be effective in producing vascularization. In the optical section of the cornea produced by the slit-lamp beam it is often possible to locate accurately at what level the new-formed vessels arise. When partial loss of transparence makes this difficult, the general pattern of branching is very helpful. The blood vessels grow between groups of corneal fibers and their pattern is determined by the grouping of fibers of the corneal stroma. In the superficial portions the fibers are an interlacing network of bundles arranged in divergent planes, while in the deeper strata they are arranged in planes parallel to the corneal surface. Consequently, very deep vessels all lie in one plane and are level bound, while those in the superficial stroma are angle bound because the vascular loops diverge from one another as they follow spaces between diverging of the bundles. Holger Ehlers has published excellent pictures of this characteristic arrangement.

The presence of vessels gives some information as to the length of time the corneal disease has existed. It takes at least six weeks to develop pannus.

The vessels for the most part are an advantage in that they increase the resistance of the cornea to invasion. They may be at times distinctly harmful and then their destruction may become

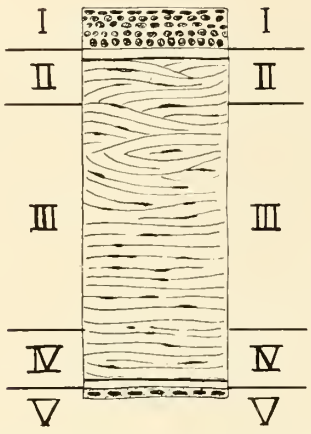

Fig. 6. Diagrammatic cross section of the cornea which shows the five zones, each of which is characterized by definite pathological reactions.
The arrangement of fiber bundles indicates the reason for the development of angle bound and level bound branching of corneal blood vessels.

therapeutically necessary. This is not only true when a vessel is so large that it is optically obstructive: in allergic lesions such as vascular fasciculus the blood vessel brings new antigens to the site of the disease so that the destructive process is kept active.

Prognostically one observation may occasionally be useful. When the question of enucleation for chronic intraocular inflammation arises the presence of vessels in a cornea that was not the primary seat of inflammation makes it almost certain that the eye will not recover, and the necessity of enucleation is confirmed.

Modifications and Transparence

In almost all corneal disease there is modification of transparence. There are differences in the character of the opacities which are important to note, but the most fundamentally useful fact is the recognition of the observation that the cornea may be divided into five layers which are distinguishable histologically and that each seems to have definite clinical manifestations associated with it.

These are:

1. The epithelium. Its histological and clinical independence is obvious and bio-microscopical study has revealed that some of the hitherto unexplained deeper lesions of the cornea are merely sequelæ of a process primarily in the epithelium.

2. Bowman's membrane and the superficial layers of stroma. Lesions of this region often coexist with those of region one, but scarring may remain here after the epithelium is entirely healed.

3. The middle lamellæ constitute three-quarters of the thickness of the cornea, and is least often the seat of disease. Often zones 2 and 4 may both be involved while zone 3 remains intact. It is its extreme resistance which sets this layer apart.

4. This zone consists of the deepest stromal lamellæ and Descemet's membrane. It plays the principal role in some of the most important diseases of the cornea. Here parenchymatous keratitis of hematogenous origin makes its first appearance, even when it later involves the superficial layers, and after healing such vestiges as scarring and microscopic vessels are usually found in this zone. It reacts with the greatest facility to superficial infections and also to deep inflammations which come from the iris and anterior chamber.

5. The endothelium, though histologically a part of the cornea, reacts pathologically with the iris and anterior chamber.

For purposes of diagnosis, then, lesions are predominantly epithelial, superficial or deep. It must be emphasized that any clinical picture of corneal disease may be complicated by scars and blood vessels (obliterated or active) which are remains of a healed lesion of an entirely different sort.

The group of diagnostic entities in which the clinical manifestations are epithelial or first manifest in the epithelium are:

(a) superficial punctati keratitis
(b) dentritic keratitis
(c) recurrent erosion
(d) filiform keratitis
(e) edema and bullous keratitis
(f) epithelial dystrophy
(g) a group of diagnostically related manifestations whose diagnosis usually depends on the observation of other manifestations, namely
    (1) xerophthalmia
    (2) lagophthalmia
    (3) keratitis neuroparalytica
(h) papules in allergic states such as phlychemtes, vernal catarrh
(i) foreign body

It would not be fruitful to comment pedantically on each of these diagnostic units. Instead, I shall mention only the more interesting phenomena, which make some of the pictures conspicuous.

Superficial punctate keratitis, dentritic keratitis, keratitis bullosa and recurrent erosion hardly need more detailed description than is contained in the name. An important characteristic they have in common is the fact that all may be manifestations of herpes. The recognition of this fact is important because it is presumably true that they may be cured if the virus is destroyed with the affected epithelium while it is still limited in its distribution to that tissue. Later, the virus may cause deep-seated lesions which may destroy vision. The virus is neurotropic and dermatotropic. By inoculation into the central nervous system of rabbits the neurotropic properties may be greatly increased and by warming it, it will return to its dermatotropic state. It is even possible that some cases of herpes zoster are caused by this virus. The most characteristic herpetic lesion is dendritic keratitis with its branched irregular linear lesions. The lesions may go deeper in the form of little gray ulcers but the linear contours of map-like irregularities are always suggestive. The serious complication of herpetic infection is keratitis disciformis, whose diagnosis will be discussed with other lesions of the deeper lamellæ.

Some of these same lesions are often non-herpetic. Keratitis punctata superficialis is the common reaction of the epithelium to any irritant and is a frequent accompaniment of acute conjunctivitis. Keratitis filiformis needs special mention because it has recently become clear that in many cases of keratitis filiformis the characteristic corneal lesion in which partially detached cell masses of the epitheium are wound into threads by the winking of the lids, is only one part of a syndrome. It occurs for the most part in elderly women, because the cornea is dried for lack of tears, which results from an atrophy which involves the lacrymal glands, as well as the salivary. Though therapy is unsatisfactory, the diagnosis may at least be made. A strip of filter paper properly placed between the lids becomes only slightly moistened in five minutes, while a similar piece placed in the eye of a normal control quickly becomes thoroughly wet for a distance of several centimeters.

Epithelial dystrophy is a rare disease which never occurs much until forty years of age and is usually bilateral, though a patient is occasionally observed when only one eye is involved. The epithelium in the paraxial portion of the cornea becomes dull and slightly turbid. Later vesicles or blebs form which rupture and cause a small loss of substance. Later the anterior stroma may become faintly gray. Characteristically the disease is a degeneration of both epithelium and endothelium and when in doubt about the diagnostic interpretation of the epithelial lesion, the characteristic holes in the endothelial mosaic when viewed in specular reflection confirm the diagnosis. Eventually the entire corneal surface becomes involved. The group of diseases which includes xerophthalmia, lagophthalmia and keratitis neuroparalytica all start with opacities in the epithelium, but soon involve the deeper tissues as well. The differentiation is made by consideration of the other effects of the causative agent which is respectively Avitaminosis A, inability to close the lids, and sensory paralysis of the branch of the fifth nerve which contains the afferent fiber from the cornea.

The Lesions which Involve Bowmann's Membrane and the Superficial Stroma

The lesions which involve this portion of the cornea may be considered in groups, the members of which have certain characteristics in common.

I. Foreign body with its ring of siderosis
   Trachoma
   Rosacea keratitis
   Phlyctenule and vascular fasciculus
   Vernal catarrh
II. The large group of ulcers
   Serpentic ulcer
   Annular ulcer and ring abscess
   Marginal ulcer
III. Rodent ulcer.
IV. Subepithelial striation from hypotony.
V. Familial dystrophies
   Band keratitis

The only lesion of the first group that needs comment is rosacea keratitis. It has recently come to notice that some cases respond to treatment with riboflavin. Its diagnosis occurs in a number of forms, namely—(1) marginal ulcer; (2) a subepithelial infiltrate which may be confused with phlyctenular disease; (3) a severe progres-

sive form that resembles rodent ulcer. Rosacea keratitis is probable when the suspected lesion is accompanied by acne rosacea of the face, when the vascularization is strikingly sparse but consists of a few thick vessels, when there is a tendency for the lesions to soften and become incrusted with calcium and if the lesion is very persistent and recurrent.

There is a peculiar arrangement of the vascular tissue which is very suggestive of rosacea. The vascularized tissue is slightly raised above the level of the surrounding cornea. All vessels end at the same sharp line of demarcation, where the tissue surface drops directly and vertically to the normal cornea level. The subepithelial rosacea infiltrates are not limited to the periphery but occur anywhere on the cornea.

Great care must be exercised in the differentiation of extensive progressive and destructive rosacea from rodent ulcer. With the latter the advancing edge is always undermined, while in rosacea the advancing edge is thickened and presents the appearance of an irregular linear mound.

The ulcers which involve this stratum do not need detailed description. The seriousness of the violent inflammation which characterizes the exogenous ulcer of serpentic type and contrasted with the milder smouldering endogenous marginal ulcer is well known. When caused by penumococcus, the organisms are best cultured from the base of the ulcer and the greater intensity of the opacity in the base often suggests the etiology. Diplobacillus also may cause a serpentic ulcer, but it causes greatest damage and densest infiltration at the sides. Occasionally similar ulcers are caused by streptothrix or mold. They may run a typical stormy course with hypopyon or may produce a milder reaction that results in a lesion that must be differentiated from disciform keratitis. The diagnosis can only be made by lifting out the mycelium and identifying it microscopically.

A special diagnostic problem is the annular ulcer and ring abscess. A number of cases have appeared in the literature from time to time. Though they doubtless do not represent a single clinical entity, they do show two characteristics. The opacity that occurs is ring-shaped and the lesion is distinctly more dangerous than a similar change which does not completely cut off the corneal center. Even the usually mild marginal ulcer, when it surrounds the entire margin, needs careful watching and may necessitate decompression of the anterior chamber. More severe and dangerous is a ring that develops farther from the margin in old trachoma eyes with pannus, often long after the conjunctival lesion has healed. The ring-shaped opacity becomes completed very quickly once the process has started and usually the eye can only be saved by prompt keratotomy. Most fulminating of all is the rare ring abscess. This disease is characterized by the development of an annular pyocenic infiltration of the stroma which develops quickly as a single lesion, not merely as an ulcer that progresses till it completes a circle.

It may follow any perforating or non-perforating injury and has even been reported after incision for cataract. The eye is usually lost through panophthalmitis.

The clinical picture of rodent ulcer is characteristic, especially if one remembers that it is a superficial, smouldering, destructive lesion that gradually involves the entire corneal surface after a start at the limbus. The advancing edge is always undermined and a rather irregular fine grey line. It is usually unilateral, very painful and usually seen in debilitated persons.

The familial corneal dystrophies are lesions that are characterized by gradually increasing opacity in the most anterior stroma lamellæ, which reduce visual acuity. There are three distinct types and there are not transitions between them. They have certain characteristics in common. They all begin in youth in both eyes and not uncommonly develop symmetrically. Painful attacks may occur in all of them. The three types are: (1) granular; (2) macular; (3) lattice.

The *granular* is characterized by dominance in inheritance. The opacities start as fine white points arranged in a radiating line, which, in the course of time, coalesce to form larger glassy white granular opacities of many shapes. By the time the patient is thirty or forty, a central disc of the cornea is fairly filled with discrete opacities. A marginal zone 2-3 mm. wide always remains clear, and so does the tissue between the granules. The epithelium always remains intact, though later it may project over granules. Corneal sensitivity is often reduced in spots. Corneal vessels do not develop.

The *macular* form is recessive in inheritance, hence becomes manifest in inbred families. It

starts early and the cornea is seen to be slightly turbid. Soon ill-defined discrete opacities develop in the turbid layer. They are larger than the opacities of type I and not sharply defined. The lesion occupies the entire corneal area. There is no clear marginal zone. The epithelium is intact, though it may project over opacities as in type I. Vascularization does not occur.

The lattice dystrophy is dominant in inheritance and is very rare. It begins a little later in life than the other two, usually in the second decade. In the beginning, the cornea looks grossly normal, though in focal illumination the surface is slightly dull and may even stain slightly with fluorescin.

The slit-lamp reveals countless fine threads, sometimes dichotomously branched, which in retroillumination give the impression of microscopic clefts. These lattice fibers occur particularly in an intermediate zone. The periphery remains entirely clear and the fibers decrease greatly in number toward the center. The lattice fibers are transparent and refractile and between them are innumerable fine granules. The surrounding corneal tissue in which they are imbedded remains clear. In middle age the hitherto clear central cornea becomes the seat of a discoidal opacity that is grossly visible. In the optical section it is seen that the lattice fibres are optically empty canals (in contrast to the corneal nerves), transverse the stroma at angles rather than parallel to the surface and involve fairly deep layers of the stroma.

The epithelium becomes rather uneven and produces an irregular astigmatism. The visual acuity is greatly reduced, usually to 20/200 in the fourth decade. Inflammatory episodes are not uncommon and are the result of epithelial erosion.

Lesions of the deepest stromal lamellæ and Descemet's membrane, the typical deep stromal layer, are: (1) parenchymatous keratitis; (2) keratitis annularis, a manifestation of 1; (3) keratitis disciformis, and (4) keratitis pustiliformis profunda.

By far the largest portion of parenchymatous keratitides are luetic in origin. The disease picture is well known and characterized by loss of transparence in the deeper strata from cellular infiltration and edema. The first stage is best observed in the second eye where a delicate veil-like opacity of the deepest lamellæ or Descemet's membrane may be seen when the eye is still free from all irritation and perfectly pale. These opacities are almost always peripheral and gradually spread to the center. Usually a few fine postcorneal deposits appear and it takes up to five weeks before opacities become grossly visible and the first signs of hyperemia become manifest. The vascularization also begins characteristically in the deepest strata. In later stages the entire cornea may become opaque and vessels proliferate at all levels. In those which heal, the last vestiges that remain are delicate opacities and collapsed vessels on the Descemet's membrane.

Positive Wassermann reaction and the presence of other manifestations of congenital syphilis aid in the diagnosis. Rarely a similar lesion is observed in acquired syphilis, but also in the complete absence of syphilis the cornea may be similarly involved. Such cases have been reported after grippe, parotitis and other general infection diseases.

Tuberculosis is also the cause of a parenchymatous keratitis. This etiology is suspected when the Wassermann is negative and Mantoux positive, and when certain characteristics of the lesion itself that suggest tuberculosis are present. A tuberculosis lesion is usually central, that is, paraxial and is much less diffuse, so that it gives the impression of being a focal lesion. The vascular supply consists not of innumerable thin vessels that come from all about the periphery but of a few stout stems whose terminal branches surround the lesion, glomerulus-like.

Occasionally in syphilitic keratitis the opacities are so arranged that they form an opaque ring in the depths of the corneal stroma. The lesion is then called keratitis annularis. The lesion may occasionally be mistaken for keratitis disciformis and the resemblance may be very great. The latter is a complication of herpetic corneal disease. The outstanding characteristic is a cream-colored disc or ring in the deeper corneal stroma. It may also be vascularized but usually other characteristics of spyhilitic keratitis such as delicate opacities and vessels in other parts of the cornea, or syphilitic keratitis in the fellow eye accompany a syphilitic annular lesion. In the slit-lamp picture keratitis annularis consists of groups of small granules, while the ring of keratitis disciformis consists of cloudy particles.

Keratitis pustiliformis profunda usually causes no diagnostic difficulty. It is characterized by the appearance of a small group of tiny pustules on

Descemet's membrane all surrounded by a delicate veil-like opacity. It is not common, but is usually seen in males near forty and is a manifestation of syphilis.

There are a few lesions of Descemet's membrane that should be mentioned. Frequently in severe intraocular disease, particularly when there have been disturbances of intraocular pressure, folds develop which are easily recognized by their double contour. Ruptures of the elastic membrane are seen after trauma. A rarity is the network of glassy fibers that may traverse the anterior chamber. They are like Descemet's membrane in structure and may be covered with endothelium. A not uncommon senile finding is the development of excrescences that are analogous to Drusen. They may be recognized by their effect on the endothelial mosaic when observed in specular rezection.

Endothelial dystrophy has been mentioned as an integral part of epithelial dystrophy.

EUSTACHIAN TUBE FUNCTION AND DEAFNESS

J. R. LINDSAY, M.D.

Chicago, Illinois

THE importance of the state of eustachian tube function becomes evident when it is realized that the major cause of deafness in early years is inflammatory disease of the tube and this type provides the main opportunity for reducing disability due to impaired hearing.

Deafness due to inner ear disturbance, congenital or acquired, is much less frequent in the child and since these types are not amenable to treatment they become chiefly an educational problem. Also otosclerosis which causes disability frequently in early adult life can neither be prevented nor cured, and is an individual problem not related to eustachian tube difficulties.

Fig. 1. Cross section of the eustachian tube in the cartilaginous portion. The lumen is slit-like, supported by cartilage, except for the lower lateral two-thirds of its wall. C. Carotid artery. F. Connective tissue and fat. M. Muscle fibers.

middle ear. Not only does the restoration of normal function of the tube constitute the greatest factor in prevention of such deafness, but the early recognition and treatment of deafness of

From the Division of Otolaryngology of the University of Chicago. Presented in Symposium on Eye, Ear, Nose and Throat Diseases at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

The chief avenue for preventing and reducing hearing disability lies in the early recognition and adequate treatment of conditions which impair eustachian tube function.

reviewed. The bony portion of the tube is about 12 mm. in length in the adult and the cartilaginous portion about 24 mm. The cartilage has the form of an inverted J (Fig. 1), the anterior end

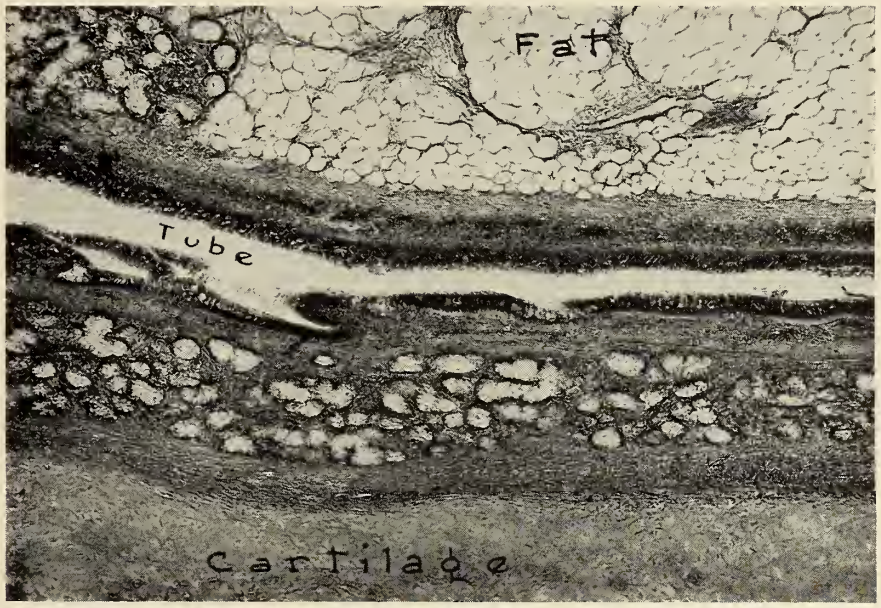

Fig. 2. High power magnification of the eustachian tube in the cartilaginous portion to show the columnar ciliated epithelium, the mucous glands, connective tissue and fat.

Fig. 3. Horizontal section through the superior border of the eustachian tube showing peritubal cells. Some fibers of the tensor tympani muscle which lies above and medial to the bony part of the tube are seen. M.E. Middle ear. C. Carotid artery.

Anatomy

In order to understand the physiology of the tube certain pertinent anatomical features may be

forming the Torus Tubarius. The tube lumen appears as a vertical slit in cross section. The inferior lateral wall is supported by connective tissue and is subject to the action of a group of

muscles, the levator veli palatini, the tensor veli palatini and the salpingo pharyngeus.

The tube is lined by ciliated columnar epithelium in the cartilaginous and bony portions (Fig. 2). The cilia disappear as the middle ear is reached. The peritubal cells (Fig. 3) vary in size and number, some being lined by an extension of the ciliated epithelium of the tube, others by cuboidal or flattened epithelium. The mucosa of the cartilaginous portion has many mucous glands.

It is obvious from the anatomical arrangement that the tube is equipped with an active mechanism for keeping moist and sweeping excess secretion toward the pharynx by ciliary action, also that the structure of the cartilaginous portions makes possible the efficient closure of the tube unless during the active pull of certain muscles, thereby providing a mechanism for protection and isolation of the middle ear from infections, noises and pressure disturbances in the pharynx.

Physiology

While the tube was named after the Italian anatomist Eustachius of the sixteenth century it is only in recent times that the function has been well understood.

Toynbee[7] of the Cornwall infirmary in England was the first to show in 1853 that the tube is normally closed. He thought that the sense of fullness in the ears produced by swallowing while holding the nose closed was due to air being trapped in the middle ears. This became known as Toynbee's maneuver. The fact that it was necessary to swallow to relieve the sense of pressure indicated to him that the tube opened during the act of swallowing.

It was Politzer[5] who in 1864, by means of a manometer sealed in the external canal, showed that Toynbee's maneuver caused an inward movement of the drum due to removal of air from the middle ears.

Jago,[3] working with Toynbee, supported the observation that the tube is normally cosed in a classical series of observations on himself on a group of symptoms which he correctly interpreted as due to a continuously open tube.

Hartmann[2] in 1879 had worked out basic quantitative data on eustachian tube function with the use of the pressure chamber and manometers. He made the following observations:

1. Increase of pressure to 130 mm. Hg. would not force the tube open but resulted in a sense of extreme pressure and pain in the ears. Only by active swallowing could the symptoms be prevented.

2. Rapid decrease of the pressure caused a spontaneous exit of air through the tube beginning when the pressure was lowered 30 mm. Hg. below that of the middle ear.

3. In order to inflate the ear by Valsalva's method a pressure of 20 to 40 mm. Hg. was normally required. During phonation of the vowels the resistance to inflation was reduced from 32 to 12 mm. Hg. and also that flexing the head on the chest increased the resistance.

In 1936, Zöllner,[9] in attempting to determine criteria for normal tube function in candidates for aviation service, reported quantitative studies of pressure required to inflate the middle ear during swallowing.

He found that the tube doesn't open entirely but that positive pressures of from 0.5 to 4.0 mm. Hg. in the nasopharynx are sufficient to inflate the ear during swallowing with the patient in the erect position.

Politzer believed that the tube opened during swallowing because a vibrating tuning fork held in front of the nose until it could no longer be heard could again be heard upon swallowing and his observation had been universally accepted.

Dr. H. B. Perlman[4] of the University of Chicago has investigated this problem among others by recording the sound transmitted through the eustachian tube to the middle ear and found that normal individuals varied, the tube apparently opening in some and requiring definite pressure differences in others to produce opening during swallowing as reported by Zöllner. The entry of air into the ear was determined by the auscultation tube or observation of the drum.

Perlman, by using a simple mercury manometer, confirmed Hartmann's observations that 20 to 40 mm. Hg. positive pressure are necessary to inflate the ear by Valsalva's maneuver. Also he found that exercise temporarily reduced the pressure required, while on assuming the prone position the necessary pressure was greatly increased so that almost no one was able to inflate the ears in this way.

This test was adapted by Perlman as a means of objectively demonstrating the condition known as "abnormal patency."

Another method for obtaining information on eustachian tube function, by measuring the pressure differences between middle ear and outer air is the "pneumophone" described and used by Van Dishoeck[8] of Amsterdam.

This consists of a water manometer connected with the outer ear, along with a transmitted tone of constant intensity so that the hearing can be tested during alterations in pressure.

He found the hearing is normally best when the pressures are within a range of 4 cm. of water while greater differences produced impairment.

By this method existing pressure in the middle ear can be estimated by the increase or decrease in pressure in the outer canal necessary to obtain the best hearing, and the difference in pressure thereby determined gives an index of tube function.

Armstrong and Heim[1] at Wright Air Field have reported detailed observations during ascent and descent, made in the pressure chamber, confirming in principle the observation made earlier by Hartmann. They found that during ascent the tubes spontaneously open at an elevation of 500 feet corresponding to a decrease of 15 mm. Hg. pressure below that at sea level and again at each additional 435 feet of elevation.

On descent the tubes do not open spontaneously. Swallowing, yawning or a similar movement of the palate is necessary to allow equalization of pressure. Lacking such action, when the outer pressure increased to 90 mm. Hg. above that of the middle ear the tube cannot be opened voluntarily by swallowing. At still greater pressures the drum may rupture.

The application of these facts to commercial aviation is that inconvenience is likely to be caused to passengers with poor eustachian tube function during rapid descent and consequently the ratio of descent has been limited to 500 feet per minute by the CAA.

During sleep swallowing occurs only about once per minute and sleeping passengers are likely to have more difficulty during rapid descent. The same applies to unconscious individuals. These physiological facts apply in the same way to caisson workers and divers. Congestion of the tubes during a cold may make it impossible for the individual to tolerate the customary rate of increase in pressure and the individual is incapacitated on that account.

Diseases Due to Rapid Changes in Air Pressure

I. *Acute Aero-otitis Media.*

This term has been coined by Armstrong and Heim to indicate the middle ear disturbance resulting from failure of the eustachian tube to open during an increase of outer air pressure.

After the negative pressure in the ear reaches 80 or 90 mm. Hg. relief is obtained only by returning to the higher altitude. Trauma may already have been produced, however, in which case the symptoms will persist after the pressure is equalized. The trauma may consist of acute congestion of the middle ear mucosa, hemorrhages in the mucosa or into the cavity or exudation of clear fluid. Symptoms vary from a blocked up feeling in the ears, to discomfort, pain and deafness. The hearing loss due to difference in air pressure alone affects mainly low tones but as fluid fills the middle ear higher tones are also affected. The Rinne test is negative. Objectively the drums are retracted and vessels are injected presenting an appearance similar to an infectious process but suppuration does not occur.

Treatment consists in inflation to equalize pressure, local heat, and shrinkage of the tube opening.

Prophylaxis consists in: (1) selection of personnel with normal tube function; (2) proper instruction regarding opening the tubes; (3) limit flying during acute upper respiratory inflammation.

II. *Chronic Aero-otitis Media.*

It is fairly common to find that individuals subjected to repeated aural trauma, as in caisson workers, divers and aviators, develop chronic symptoms of stuffiness, head noises, and difficulty in clearing the ears by efforts to open the tubes.

Objectively some degree of retraction and thickening of the drums is evident. The type of deafness, however, is apparently a combination of conduction and inner ear types. The inner ear type is known to exist in caisson workers who have not been exposed to acoustic trauma but in the case of fliers the chronic hearing impairment is likely to be due to two factors, inner ear damage from repeated acoustic trauma and middle ear changes from inadequate tube function.

Treatment consists in removal of predisposing factors such as chronic inflammations in the nose and throat and possibly treatment for relief of tubal stenosis.

Tests for Tubal Function

The need for accurate means of estimating tubal function has become apparent with the increase in aviation. The methods which have been available for many years have been: (1) Valsalva's maneuver, using the auscultation tube or watching the drum for bulging; (2) swallowing to see if the bulge is relieved; (3) if the bulge doesn't disappear, as may occur if the pressure difference is too small, trying Toynbee's maneuver; (4) if both maneuvers fail Politzeration may be done during phonation or swallowing and if this fails, the eustachian catheter may be tried.

These methods have given fairly dependable information in experienced hands but in more recent years more accurate methods have been developed for determining tubal function under certain conditions. The method described by Zöllner, to measure the pressure needed to open the tube during swallowing, and the pneumophone, by Van Dishoeck, for estimating middle ear pressure, represent improvements designated to obtain reliable objective information.

Perlman has recently devised an apparatus based on a combination of that of Zöllner and Van Dishoeck so that an objective measurement can be made of: (1) the pressure necessary to open the tubes by Valsalva's maneuver; (2) the pressure necessary to inflate the ear during swallowing; and (3) the degree of positive or negative pressure existing in the middle ear. The performance of inflation by a measured amount of positive pressure in the nasopharynx during swallowing accomplishes at the same time the objective of inflating the ears in a simple controlled manner, not unpleasant, without the need of instrumentation. The apparatus which will be described by Perlman along with detailed observations in the near future, seems to promise a more accurate and simple method of evaluating tubal function.

Diseases Arising from Impaired Tubal Function

The clinical conditions which have their basis in a disturbance of function of the eustachian tube can be divided into three classes: (1) abnormal patency; (2) acute inflammatory processes affecting the tube and middle ear; (3) chronic inflammatory conditions of the tube and middle ear.

The question of acute and chronic suppuration of the middle ear spaces and the deafness resulting therefrom does not come within the scope of this discussion and is therefore not covered except for occasional reference.

1. *Abnormal patency.*

Jago[3] of Cornwall in 1867 and Rumbold[5] of St. Louis in 1873 gave accurate descriptions of this condition. Perlman[4] presented further observations in 1939. Under normal conditions the tube is closed with sufficient firmness to protect the ear against common pressure changes in breathing, sneezing, and coughing as well as the acoustic oscillations incident to the same actions and to speech.

Abnormal patency may vary from the continuously open tube to that which opens more easily than normal. The former condition exposes the ear to the pressure changes in the nasopharynx and the drum may be seen to move out and in with respiration and a blowing sound heard through the auscultation tube. The nasal sounds "in," "m," "ing" can be clearly heard with the diagnostic tube (autophony). In tubes with a lesser degree of abnormal patency the tube may remain open only at intervals or during sneezing and nose blowing which causes considerable discomfort. Hearing is impaired while the tube is open, due to masking effect of the noise from the pharynx.

The condition is not frequent. It is likely to be found in thin individuals, particularly women who have lost weight. A recent case was observed in a young woman in the later stages of pregnancy, persisting for some months afterwards. It is a common occurrence after retrogasserian neurectomy of the fifth nerve.

Such patients characteristically hear well when they lie down, since the tubes close when they are in the recumbent position.

Treatment of such patients is limited to the use of the eustachian catheter and such medicaments as will stir up a mild inflammatory reaction, for example, insufflation of boric and salicylic acid powder.

Restoration of weight loss may relieve the condition in some cases.

2. *Acute eustachian salpingitis, acute nonsuppurative otitis media, acute bullous myringitis (myringitis bullosa).*

Acute eustachian salpingitis is diagnosed mainly on the subjective complaint of a stopped-up

feeling in the ear or, in the case of a deaf person, an increase in deafness during a head cold or acute inflammatory reaction in the nasopharynx and nose, while there are still no recognizable changes in the drum.

The hearing loss may be difficult to demonstrate objectively, but measurement with the "pneumophone" of Van Dishoeck may show abnormal pressure in the middle ear.

The process represents the first stage of extension of an inflammatory process from the nasopharynx and is still reversible. Treatment is directed to the upper respiratory condition with warning against strenuous nose blowing. Elevation on pillows with the affected ear up during sleep helps reduce congestion.

Acute nonsuppurative otitis media represents an extension of the inflammatory process into the middle ear, producing recognizable changes in the drum. The inflammatory process may still be arrested in this stage and restitution occur. In severe infections and with favorable predisposing conditions invasion by the infecting organism occurs. The tube then becomes blocked or incapable of carrying off the inflammatory products, and suppuration develops.

Impaired hearing and ear noises become pronounced as the middle ear is involved and pain may occur. The latter may be coincident with formation of bullæ in the drum, which are filled with serum or hemorrhage.

Treatment in this stage is directed to control of the infection within the nose and throat with no local interference in the ear except as necessary for relief of pain. Since it is a matter of great importance to prevent extension of suppuration into the middle ear spaces the use of sulfonamide therapy in this stage seems definitely indicated in selected cases. Such therapy must be carried out in adequate concentration with careful control of fluid intake and output, urine and blood examinations and observation for signs of reaction or toxicity. Usually treatment for about three days is sufficient and if given promptly in this stage, suppuration rarely develops. Elimination of predisposing factors such as adenoid hypertrophy in children or chronic sinus infection is an essential prophylactic measure after the acute stage.

Acute exudative catarrh is a variety of acute nonsuppurative otitis media which is fairly common. The middle ear and sometimes the whole air-cell system fills with clear fluid. The drum may show some injection but is mainly more

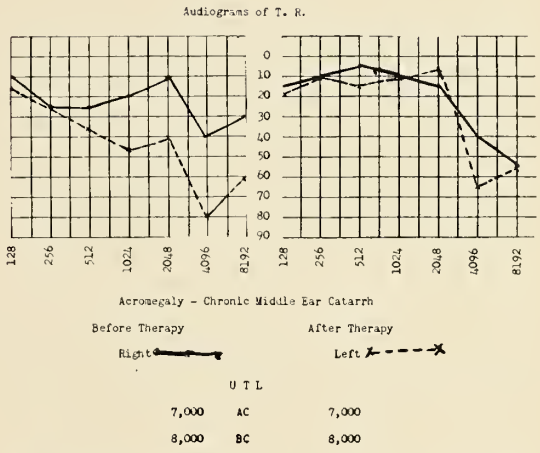

Fig. 4. Impaired hearing due to chronic nonsuppurative changes in the tube and middle ear (dry type) occurring in acromegaly. Impairment up to 2000 cycles is due to conduction loss. The high tone loss and lowering of upper tone limit (UTL) is to be explained partly by acoustic trauma, and probably partly by primary nerve degeneration.

transparent with the malleus appearing narrowed. Fluid lines are absent if the middle ear is entirely filled.

Hearing impairment for the voice is marked.

In cases of this type spontaneous resolution usually occurs. However, if some predisposing factor such as adenoid hypertrophy, chronic rhinitis or sinusitis is present the condition is likely to become chronic. It is my policy not to inflate or attempt to remove fluid from this type of ear until the fourth week. Most cases subside in the third or fourth week spontaneously. Before this time inflation alone gives only temporary relief while the removal of the fluid by puncture of the drum and inflation may introduce infection and suppuration.

Bullous myringitis is another division of nonsuppurative otitis media, in which the formation of bullæ on the drum filled with serum, sometimes with hemorrhage, is the chief local change. Pain occurs, and slight discharge with rupture of bulla. This condition is said to be more characteristic of influenza infection, but is commonly seen in other types.

Chronic Tubal Obstruction and Nonsuppurative Otitis Media

Under this general heading two distinct types may be differentiated: (1) dry catarrh, chronic adhesive processes, et cetera; (2) wet catarrh or chronic exudative catarrh.

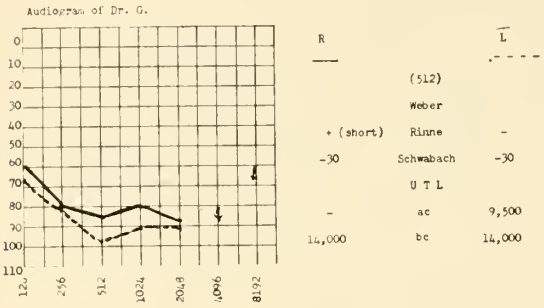

Fig. 5. Marked deafness due to chronic suppuration bilateral now healed. Eustachian tubes stenosed. Marked relief from tinnitus follows bouginage and inflation. Uses a hearing aid.

Dry Catarrh.—Under group 1 is included those cases of chronic conduction deafness occurring as a result of recurring inflammatory attacks, some of which may have been suppurative, others nonsuppurative.

The pathological process consists of varying degrees of impaired eustachian tube function, thickening, retraction, and scarring of the drum and fibrotic adhesions involving the conduction apparatus.

Deafness varies with upper respiratory infections and is temporarily improved subjectively and objectively by inflation of the middle ear (Fig. 5). Treatment consists in correcting any predisposing factors in the nasopharynx and nose such as hypertrophied adenoids, chronic nasal and sinus disease. Children seldom require more than removal of the cause of the tubal obstruction but in the adult varying degrees of stenosis may have developed, and some improvement in tubal function may be obtained by judicious use of bouginage. Patients may experience enough relief from tinnitus and hearing impairment to warrant periodic treatment (Fig. 6).

Chronic Exudative or Wet Catarrh.—This type is characterized by a persistent or recurring collection of fluid in the middle ear and its connecting air spaces. The fluid completely fills the middle ear and fluid lines are not visible. Diagnosis can be made on the appearance of the drum, the distinctive signs being the increased transparency of the membrana propria due to the fluid medium against its inner surface and a consequent narrowing of the handle of the malleus which then appears as a thin chalky line broadened at the umbo.

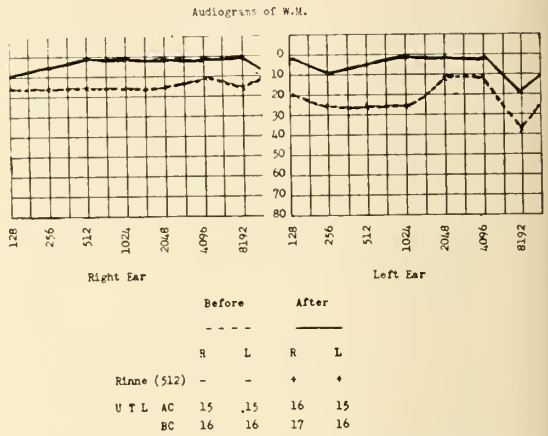

Fig. 6. Bilateral chronic exudative catarrh in child of 3 years. Spontaneous disappearance of the fluid within one month after adenoidectomy and tonsillectomy.

Deafness is of the conduction type with a greater loss for high tones than in simple dry catarrh or early otosclerosis.

The direct cause of this type is an abnormal degree of tubal obstruction, indicated by its consistent appearance in obstruction by nasopharyngeal tumor, and its frequency in cases of obstructing adenoids.

The negative pressure theory of Politzer and Zaufal offers the best explanation of the replacement of air in the middle ear spaces by fluid and is supported by the finding of a negative pressure by the pneumophone. The fluid is usually thin but sometimes becoming viscid, suggesting a high mucinous content. The condition is found most frequently in children due to obstruction of the tubes by adenoids. It is also characteristic of nasopharyngeal tumor, and may occur in chronic sinusitis or rhinitis. Some individuals have recurrent attacks with upper respiratory infections, probably on the basis of chronically impaired tubal function.

In children the removal of the predisposing cause is usually followed by spontaneous recovery of the ear in three to four weeks (Fig. 7). Removal of fluid from the middle ear by puncture and inflation of the tube is rarely necessary.

Bilateral deafness of this type is usually de-

tected in the child either at home or in school, but it is a frequent occurrence that unilateral deafness of this type will be undetected or neglected for years unless the other ear also becomes impaired.

With the almost universal use of sulfonamides during acute infections, suppurative disease of

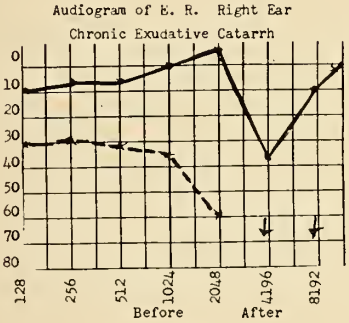

Fig. 7. Recurrent chronic exudative catarrh due to chronic changes in the eustachian tube. The orifice appears normal. The broken line shows the hearing threshold before and the solid line after the removal of the fluid from the middle ear. Recurrence tends to occur in two to three weeks.

the ear is frequently prevented or cured, but a residual unilateral deafness may be neglected, partly because the young child does not complain and partly because the local signs exhibited by the drum will only be recognized by the trained observer.

While removal of the obstructing adenoids or relief of a sinus infection usually results in spontaneous recovery in the child, the adult may not respond so well, probably because of chronic changes in the tube, and may require aseptic puncture of the drum and inflation to expel the fluid. A dramatic improvement in hearing follows, but recurrence is likely unless causative factors are corrected.

In conclusion it may be emphasized that attention to those factors which impair function of the eustachian tube in the childhood stage offers the chief means at the present time of prevention of deafness in later life.

The development of new and refined methods for determining eustachian tube function will contribute much to the improvement in diagnosis and intelligent management of this problem.

ACUTE SUPPURATIVE OTITIS MEDIA—A RECONSIDERATION

CHARLES E. CONNOR, M.D.

Saint Paul, Minnesota

THE tympanic cavity has acquired new significance in recent years as the result of anatomical research upon the pneumatic system of the temporal bone. Time was when the cavum tympani was considered an anatomical entity, and acute suppurative otitis media an inflammatory reaction therein. The mastoid process was another anatomic unit and its involvement was recognized as mastoiditis. Acute infections started in the middle ear; if not controlled, the adjoining unit, the mastoid, was involved and mastoiditis was added to the otitis. The process was considered one of progression, principally by continuity of tissue, in which the cavum tympani was simply the first in a series of anatomical structures to be involved in the suppurative process.

We now realize that, instead of playing this restricted part, the tympanic cavity has a much wider rôle, carrying with it numerous and important relationships; it is the central receiving and distributing point for infection attacking the temporal bone through the eustachian tube. We regard it as the key point in the complicated air-cell system of the temporal bone, all of which has direct relationship with the tympanic cavity.

Presented in Symposium on Eye, Ear, Nose and Throat Diseases at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

An acute suppurative otitis media involves not only the tympanic cavity but also, to a varying degree, other portions of the pneumatic system, so that the entire temporal bone is implicated; fortunate it is for us that, in most cases, the involvement of distant air-spaces is not severe, often not exceeding a mild hyperemia which tends to spontaneous resolution unless there is interference with ventilation and drainage at some bottle neck, with subsequent retention and infection.

The anatomy of the temporal bone is of more than academic interest, for upon it depends the incidence and course of many of the complications of acute suppurative otitis media and the incidence and location of chronic suppurative lesions. It has been pointed out that, in a pneumatic bone, infection involves the entire cell system to a certain degree, often so slight that spontaneous resolution occurs; when this does not follow we have the development of a clinical entity, mastoiditis, petrositis, involvement of the squamous temporal or zygomatic root. This is usually due to poor drainage, either because the communicating passages are naturally small or because they have been narrowed as the result of previous inflammation.

The intimate contact of air cells with marrow in the diploetic bone is conducive to osteitis and osteomyelitis. The membrane of the small air-cell system is, according to Wittmaack,[3] theoretically less resistant to infection; one may, however, have the involvement of distant cells and interference with drainage seen in the pneumatic bone. One is more apt to find at operation a softened necrotic bone with small cells filled with granulation tissue than the cavitation seen in well-pneumatized bone.

The sclerotic or infantile bone differs from the foregoing in that an acute suppurative otitis media is not so widely disseminated throughout the entire bone and complications so characteristic of pneumatic bone, mastoiditis, petrositis, are not frequent. The lack of a cellular system is apt to localize infection in the middle ear, and if retention does occur, it may be followed, as pointed out by Maxwell and Brownell,[1] by thrombosis of venules in the mucosa, local necrosis of the mucoperiosteum, and ultimate development of localized osteitis in the region of the attic, aditus or antrum.

The pathology of acute suppurative otitis media is fundamentally that of acute inflammation of any tissue, but there are modifying factors which influence the incidence of complications and the development of chronicity. The most important of these is retention. The longer the products of inflammation are dammed back in the middle ear the greater is the probability of local necrosis and involvement of distant air cells. This retention is caused by late drainage, either myringotomy or spontaneous rupture, both of which, but especially the latter, may be inadequate. A previous otitis may be responsible for a thick fibrous drum, slow to rupture, or a fibrous, avascular submucosa, less able to resist infection. Either or both may be etiologic in the production of chronicity. Maxwell and Brownell have shown that retention in the mastoid of pus under pressure tends to thrombosis of small vessels in the mucosa of the septæ, interference with blood supply, and ultimate bone necrosis. It seems to me entirely logical to assume that prolonged pressure in the middle ear may well interfere with circulation, cause local necrosis of the mucoperiosteum, and so lay the groundwork for a later chronic suppuration. One may well say then that retention is the key factor in the progress and prognosis of middle ear suppuration and of the incidence of its sequelæ.

Bacteriological studies of acute suppurative otitis media are numerous, many of them based on large amounts of material, carefully studied. These show the same fairly small group of organisms to be responsible, although their relative importance varies. This is to be expected, because we know that organisms responsible for respiratory infections vary from season to season, not only in incidence, but also in clinical manifestation, that is, predilection for certain tissues and types of complication.

The various streptococci, pneumococci and staphylococci play the predominant rôle, with the hemolytic streptococcus and pneumococcus III the most apt to cause serious lesions. None of these organisms, with the possible exception of the latter, is characterized by a clinical picture clear enough to permit its recognition. Occasionally an organism, not ordinarily virulent, may acquire unusual properties and produce the severest type of infection.

The bacteriological study of acute suppurative otitis media has acquired new significance since the introduction of the sulfonamides; these po-

tent drugs cannot be intelligently used without knowledge of the organisms causing the lesion. One occasionally sees acute suppurative otitis media of such threatening aspect that immediate use of a sulfonamide, preferably sulfadiazine, is warranted without waiting for a report on cultures; when this is secured, therapy may be modified if necessary.

The various methods of culture vary considerably in their efficacy; they may be taken from the external canal, from the myringotomy knife, or from the postnasal space in the vicinity of the tube. Cultures from the external canal are least reliable, the responsible organism being frequently overgrown by contamination; the longer the ear has been discharging the more apt is this to be the case. Cultures from the myringotomy knife are most apt to yield the responsible organism and do so in a high percentage of cases; those from the region of the pharyngeal end of the tube are also reliable and show the same organism as the myringotomy knife in a large percentage of cases.

There is no disease more protean or unpredictable in its clinical manifestation than acute suppurative otitis media. Certain patterns are familiar. The disease may start with mild symptoms, slight temperature, little pain and but mild injection along the hammer handle, and gradually increase in severity until a full-blown otitis requiring myringotomy is present. Or this same general course may be followed but never reach the point where intervention is necessary; there may be a small amount of purulent exudate behind the drum, but the absence of temperature and pain makes drainage unnecessary.

There is the fulminating type, starting in the mesotympanum or in the attic, but soon involving the mesotympanum, running a rapid course with high temperature, severe pain, prostration, and retention requiring early drainage. A type frequently seen is one which remains localized in the attic, with redness and swelling of Shrapnell's membrane, symptoms of moderate severity, running a slow course and finally subsiding spontaneously.

There is the necrotic type, fortunately rare, seen occasionally in scarlet fever, characterized by necrosis of drum, ossicles and occasionally the deeper bony structures of the ear, e.g., the labyrinth. And finally there is the acute otitis with early symptoms of sepsis, as evidenced by chill, peaked temperature, and prostration, fulminating from the beginning, and requiring our utmost efforts in diagnosis and therapy from the start.

One cannot tell, in the early stages of an acute otitis media, exactly what the course will be. Cases starting slowly with the comparatively mild symptoms may run a long course and ultimately develop mastoiditis or blood stream involvement; fulminating cases may quiet down quickly after myringotomy and behave very well. Daily supervision is necessary to prevent the disagreeable surprise of finding a situation much worse than anticipated.

Laboratory aids are important in the diagnosis and treatment of acute suppurative otitis media. The complete blood count with Schilling hemogram helps greatly in estimating the severity and course of the disease. The hemoglobin reading is important, especially in hemolytic streptococcus infection; a constant drop means an uncontrolled infection, as does a steadily mounting band count, or shift to the left, in the hemogram. Some surgeons of wide experience have felt that they could base operative indications on the band count, considering one of over 16 per cent as calling for surgical interference. My own opinion is that the band count, while helpful and important, is not, in itself, an indication for surgical treatment.

Blood cultures are important whenever sepsis is suspected; a negative culture or a series of them does not rule out sepsis, but a single positive establishes the diagnosis beyond doubt.

The determination of sulfonamide blood-level is important, especially in gravely ill patients or when large doses are being given. Estimation of dosage based on body weight is often the only method available, but any patient who is so seriously ill as to require intensive therapy should be hospitalized for accurate determinations.

X-ray studies are usually not indicated in the early stage of a suppurative otitis media unless there is evidence of an early mastoiditis. The mastoid and petrous tip will almost always show some clouding of the air cells and blurring of the septæ in the early stages; it is only later, in ten to fourteen days, that one expects to find definite evidence of mastoid involvement. Decalcification calls for close observation; bone destruction is a definite operative indication.

The sulfonamides have introduced an element of uncertainty into the x-ray picture of acute

suppurative otitis media in that the increased transparency of the bone caused by them tends to minimize the changes taking place, resulting in misleading x-ray findings, in that they do not reveal the true condition. This, in clinical terms, means that, in those with suspected mastoiditis who have received sulfonamides, one must be prepared to operate on patients in whom the x-ray findings do not appear to justify operation. A healthy, normally pneumatized bone is often helpful in judging the changes in the case under observation.

Even as retention is the pathological keystone in changes developing in middle ear suppuration, so it is the central point of attack in all therapy of the disease; of the many things done, only a few are helpful, their efficacy depending on the extent to which they control retention.

Medication in the external canal is, with one or two exceptions, futile. Carbolated glycerine is one of the commonest; any ear so treated should be closely observed because this preparation, while undoubtedly relieving pain, often acts as morphine in acute appendicitis, e.g., the patient is more comfortable but the lesion progresses. From a purely diagnostic point of view, it were better not to use analgesics in acute middle ear disease, because pain is here, as in many other conditions, a valuable guide. Demands, however, for relief of pain usually make such preparations necessary.

Alcohol is useful in cleansing (not sterilizing) the canal before myringotomy. Its use in an acute, discharging ear, as with the local use of various dyes and antiseptics, is completely futile; a moment's consideration will show this to be true. It is quite impossible for any liquid dropped into the external canal of an acutely inflamed ear to pass through a drum opening almost closed by swelling and through which purulent discharge is pumping under pressure, and to diffuse itself throughout an inflamed middle ear full of pus. Many things have been so used, but I am convinced that the good results reported represent the natural tendency of 90 per cent of cases of acute otitis to spontaneous resolution.

Various methods of promoting drainage have been recommended; of these, the use of dry gauze wicks might be helpful, did it not require the constant attendance of one especially trained in the technique and did not the frequent manipulation open the way for skin infection. Drywiping helps to keep the canal from being blocked, but does very little to facilitate drainage. Routine irrigations are to be avoided, because they macerate drum and canal and open the way for skin infection. Only occasionally, when pain cannot be otherwise relieved or when drainage is blocked by closure of the drum opening or by filling of the canal fundus with thick secretion, is hot irrigation called for; under these conditions it may be most helpful.

Heat in any form is useful. Hot moist packs are especially effective, but any of the usual agents, dry heat, infra-red, may be used.

X-ray, if used early and in light dosage, often seems to relieve the pain and favorably influence the course of the disease.

The sulfonamides have posed new problems for the otologist, both in the selection of cases for treatment and in the administration of the drug. As yet, there is no generally accepted method of procedure and diametrically opposite techniques are advised by men of equally wide experience.

That the use of these drugs has effected marked changes in the incidence and course of suppuration in the temporal bone, no one will deny; the exact extent and reason for these changes is not so easily defined. There is no doubt that the sulfonamides are widely and indiscriminately used in all types of head and ear infection. This undoubtedly has prevented the development of otitis in many cases of respiratory disease—how many no one can say. The lessened occurrence of middle-ear suppuration means lessened mastoiditis and intracranial complications.

The sulfonamides are variously used by men of wide experience. Some give them as soon as a diagnosis of otitis media is made and continue adequate dosage for from five to seven days. This method is based on the theory that the drug is most effective when used in the presence of good blood and oxygen supply, in the absence of peptones and disintegration products of leukocytes, and not in bony tissue; hence its use when the infection is limited to the mucosa where these conditions are fulfilled, and before it has had time to invade bony structure. Any effectiveness the drug possesses should be manifested in the time mentioned.

Others advocate giving the drug early and continuing its use until the otitis is cured or mas-

toiditis develops. This means that one must be prepared to continue its use for three weeks, the average time of discharge in 67 per cent of cases. This, to my mind, is not desirable, because of the latent danger of kidney and blood damage, sometimes cumulative. I have seen sulfanilamide used with every safeguard over a period of three weeks, only to have the clinical picture change almost overnight, with the development of a very marked and alarming neutropenia, which responded to no treatment whatsoever and proved to be permanent. This method of administration is based on the theory that discharge means infection, which is, of course, true, and that infection calls for the use of sulfonamides, which is not necessarily true.

A third method is to wait, if possible, for a period of ten days, and then, if there are disturbing symptoms, to use these drugs. This, to my thinking, is not a completely rational procedure, inasmuch as the sulfonamides are, theoretically at least, most effective in the early days of the disease. It is advocated by those who feel that these drugs mask the course of an otitis and that but few complications occur in the early days of the disease.

The development of meningitis or sepsis is, at any time, an absolute indication for the sulfonamides, but if mastoiditis, petrositis, or extradural abscess develops, the best opportunity for their control has been lost. If bone necrosis or abscess develops, the sulfonamides have nothing to offer. Followed to its logical conclusion, this method means withholding the drug until complications have occurred, which is, in fact, the method of use advocated by still another group of writers, who point out that 90 per cent of cases of suppurative otitis media recover spontaneously and that the sulfonamides, being the potent drugs they are, should be reserved for cases developing complications. It seems to me that, of these three techniques, the early administration of the drug is best supported by theoretical considerations, offers the greatest chance of benefit, and is attended by the least danger.

When one inquires more particularly into the results of sulfonamide therapy in acute suppurative otitis media, one again enters a field where definitive conclusions are hard to draw. Even as one encounters diverse opinions regarding the indications and technique of use of these drugs, so one finds the most divergent opinions regarding their effects. Some authors feel that the results are quite definite and satisfactory in that the duration of the discharge and incidence of complications are lessened. Others find these aspects of otitis but little influenced. Statistics are cited to substantiate each position. One of the recent critical studies on this point is that of Henry L. Williams[2] and associates of the Mayo Clinic, who found, among other things, that duration of discharge was but little influenced by the sulfonamides, that surgical mastoiditis occurred somewhat less frequently (by 14 per cent) in cases of hemolytic streptococcus receiving these drugs than in similar cases not so treated, that this difference in favor of the sulfonamides was increased to 17 per cent when only adequately treated cases were included in the study, that the incidence of surgical mastoiditis was much less (by 21 per cent) in cases of diplococcus pneumoniæ properly treated with sulfonamides than in similar cases not so treated, and that in 12 per cent of cases of hemolytic streptococcus infection, specific therapy was discontinued because of the development of anemia or leukopenia.

Two further points made by Williams are important. Patients who have been receiving sulfonamide therapy do not appear to develop biologic resistance to their infection. If surgical intervention becomes necessary, several days should elapse after chemotherapy is discontinued before operation is instituted. The other point, quite important, is that patients with acute suppurative otitis media should be treated in a hospital for proper supervision of the treatment.

The fact that treatment had to be stopped in 12 per cent of cases of hemolytic streptococcus infection because of the development of anemia or leukopenia serves but to stress the fact that the sulfonamides are potent drugs and should be used only on considered indication and with careful check. Not alone is there danger of damage to the blood-forming organs, kidneys, liver, skin and nervous system, but there is another danger, important because of its insidiousness: use of the sulfonamides may so mask the progress of the disease that its true status is not appreciated until the sudden appearance of some complication such as mastoiditis, extra- or subdural abscess or meningitis. The clinician must learn an entirely new set of indications for surgical interference; he must be prepared to operate on what would formerly have been considered insufficient indica-

tion, and he must be prepared to find the condition worse than clinical or x-ray studies would indicate; this is especially true in coalescent mastoiditis.

A word about another danger inherent in the use of the sulfonamides. Both laity and profession have acquired an almost naive confidence in these drugs so that they have an unwarranted feeling of security as long as such therapy is used and neglect necessary observations and studies.

How can one, in the presence of such a mass of confusing evidence, work out satisfactory indications for the use of the sulfonamides in acute suppurative otitis media? Certain truths have been demonstrated. Inasmuch as these drugs work better in the presence of abundant blood and oxygen supply they should be used early in the course of the disease, as soon as the diagnosis is made. So used the above requirements are fulfilled and complications are not masked. Also proved is the value of sulfonamide therapy in the complications of acute suppurative otitis media. Obviously, it should be used in such situations and pushed to the limit of the patient's tolerance. There remain certain other situations which call definitely for the sulfonamides. Maxwell and Brownell summarize them as follows: Any case of acute suppurative otitis media, fulminating in character, with signs of early mastoid involvement and accompanied by sepsis, profuse discharge, pain and mastoid tenderness; cases secondary to virulent infection in the upper respiratory system; early, acute rapidly-developing middle ear infections, characterized by a red, edematous tympanic membrane and thin, seropurulent or serosanguinous exudate under pressure in the tympanum; and all cases of acute suppurative otitis media due to the pneumococcus.

Even as retention is the central factor in the pathological aspects of middle-ear suppuration, so is its relief the key point in treatment. The sooner retention is relieved the better the course of the disease; the longer retention persists, the more likely a prolonged or complicated course.

Relief of retention may be either through spontaneous perforation or myringotomy; the former is more apt to be inadequate, the latter, when well performed, gives optimum drainage. Drainage may be early or late, by which we mean early enough in the course of the disease to exercise its maximum therapeutic effect, in the first three, or preferably two days, or whenever gas or fluid under pressure can be released by myringotomy. Drainage may be late, by which we mean so late in the course of the disease that its maximum benefit will not be received and damage may be done by pressure of fluid in the middle ear or backing up of secretion into contiguous air cells.

One of the best studies of the drainage question in acute suppurative otitis media is presented in a recent paper by Maxwell and Brownell of the University of Michigan, already referred to. Their conclusions from a group of 1,514 cases may be summarized as follows:

1. Late drainage (spontaneous perforation or late myringotomy) increases the incidence of surgical mastoiditis and of its complications and mortality.

2. Spontaneous perforation tends to come late rather than early, especially in children under ten, and increases the incidence of secondary myringotomy and surgical mastoiditis.

3. Early drainage varies directly with the age, and is less frequent in infancy and childhood; late drainage varies indirectly with the age, and is less frequent in later life.

4. The mortality rate increases with age in both septic and non-septic cases; a sharp increase occurs after sixty in non-septic cases and after twenty in septic cases.

5. Serious complications (parasinus and epidural abscess) and mortality rate are higher in septic than nonseptic cases.

6. Associated constitutional disease, especially nephritis and diabetes, increases the incidence of sepsis and the mortality.

The role of drainage and of methods used to effect it in acute suppurative otitis media may be summed up by saying that the earlier drainage is established, the more effective will it be in controlling the course of the suppuration, lowering the incidence of mastoiditis, complications and mortality; the later it is established, the less influence it has on the course of the suppuration, complications, the need for operation, and mortality. And, of course, it goes without saying that drainage, no matter how early or efficient, does not prevent surgery and complications or the need for operation.

The fact that over 90 per cent of cases of acute suppurative otitis media recover spontaneously suggests that the mortality rate is very low, espe-

cially in nonseptic cases. The figures show a mortality of 2.24 per cent in 729 cases of nonseptic otitis media and of 28.7 per cent in 167 cases of otitis media with sepsis. It must be remembered that these figures come from a university clinic, where many, if not most, of the cases are seen late. I am very sure that the mortality in cases seen early and adequately treated is less.

There is no doubt that the incidence of both acute and chronic otitis media has diminished greatly in the last two decades; for this a number of factors are responsible. Both laity and profession are more ear conscious and aural symptoms receive earlier and more adequate attention than in former years. The control of the acute exanthemata in infancy and childhood is another important factor, as are the wholesale tonsil and adenoid operations performed during the last twenty-five years. And now, the universal use of the sulfonamides has undoubtedly, but to an unknown extent, still further lowered the incidence of ear infections.

Much can be accomplished to still further lower the incidence of otitis. Public health education in the care of acute upper respiratory infections, in the significance of aural symptoms, and in the proper use of the handkerchief, is important. Instruction in the proper methods of swimming and diving are essential. Excessive indulgence in these sports, especially under-water swimming or prolonged swimming with chilling and lowering of body resistance, is harmful. Swimming with a drum perforation is inadvisable. Finally, those working in the field of otolaryngology have a peculiar responsibility in making sure that they do not induce otitis in patients under their care, by too vigorous inflation of the ear with resultant drum rupture, by irrigating an ear without ascertaining the integrity of the drum, and by care in the use of nasal irrigation and of nasal tampons.

STAPHYLOCOCCIC CONJUNCTIVITIS

T. R. FRITSCHE, M.D.

New Ulm, Minnesota

STAPHYLOCOCCIC conjunctivitis is a catarrhal inflammation of the conjunctiva usually more marked in the lower palpebral and bulbar conjunctiva and in the region of the caruncle. It is often bilateral and has scanty to moderate amount of discharge, is frequently accompanied by obvious lid infection and usually characterized by a mild and very protracted course with exacerbations, although it may be acute and severe and in many cases is accompanied by diffuse punctate superficial corneal opacities, and less often by catarrhal ulcers.

The causal organism is a spherical non-motile Gram-positive cell arranged in grape-like clusters on solid media and shows great variation in its biochemical activities, hemolytic power and pathogenicity. On agar the growth is orange, yellow or white. It is usually non-pathogenic, but some strains have the power of producing a powerful exotoxin to which humans may become allergically hypersensitive. When a staphylococcic infection becomes general and invades the blood stream, agglutinins occurring naturally in human plasma tend to localize the lesion. Drs. Allen and O'Brien stated that the toxic strains which incite conjunctival disease ferment mannitol, produce purple or yellow growth on crystal violet media, coagulate human plasma and liquefy gelatin.

The conjunctival sac is sterile at birth, but only about 30 per cent of adults have sterile conjunctivæ. This percentage varies widely as reported by different authors. The skin of the lower lid and the meibomian gland are the most frequent harboring place of the organism. Organisms introduced into the conjunctival sac generally lose pathogenicity and become attenuated because of the lower temperature, the lysozyme and sluicing action of the tears. However,

Presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

when the eyes are bandaged, the temperature is increased and a perfect incubator is formed, which causes an increase in the number and virulence of the organism. Staphylococcic conjunctivitis is mildly communicable and trauma shortens the incubation period. The conjunctiva once infected seldom acts as a portal for general disease and therefore does not provoke a general humoral response.

The pathologic characteristics of staphylococcic conjunctivitis are essentially the same as in other forms of conjunctivitis and consists of a hyperemia, a stasis, and an exudation of cells and fibrin-rich edematous fluid. The exudation, after producing edema or even chemosis in some cases, filters through the conjunctival epithelium, mingles with the tears and various secretions of the conjunctival glands and constitutes the discharge. At first the flow of tears is reflexly increased, then goblet cells increase their discharge, giving it a mucoid appearance, and eventually the addition of inflammatory cells makes the discharge purulent. When capillary endothelium is injured severely by the toxins, red cells may escape by diapedesis and cause the discharge to be blood tinged. As the acuity subsides, lymphocytes and monocytes appear. From the tissue a lymphocytic response is provoked in the adenoid layer; later, plasma cells, histiocytes and finally fibroblasts appear. When the superficial cells with their turf of bacteria desquamate, the intensity diminishes. The deeper cells hasten their proliferation and themselves become phagocytic and thereby the new conjunctival stratum acquires a local immunity to the toxins.

In chronic stages there is an increase of mucus from the goblet cells and downward proliferation of the epithelial cells, especially of the palpebral region where the exudation in the subconjunctival tissue forces the epithelium into papilliform elevations. Between these elevations the most extensive mucoid changes occur, starting at the bottom folds and causing invaginations having the appearance of new glands, known as glands of Henle or crypts of Dubreuil. As the central cells degenerate, the mouths of these glands may become blocked, resulting in the formation of pseudoretention cysts, which may act as harboring places for the organisms. If the process is acute, they are purulent and appear as yellow points which may rupture or should be opened. In chronic stages these pseudocysts become calcified. These cysts are most common on palpebral conjunctivæ, but may rarely be found on the bulbar conjunctivæ and then usually contain a mucoid fluid.

The clinical course may be very acute and severe with edema and dermatitis of the lids. Pseudomembranes rarely occur. In the acute cases the eyes are congested, a mucopurulent discharge is present, the eyes are sensitive to light, have a scratching sensation and may be very painful during the time that the cornea is affected with a superficial keratitis of minute epithelial defects which stain with fluorescein. Mild iritis may at times be present. The lids are often red and thickened, and may have a distinct blepharitis. The conjunctiva of the lower lid, fornix and caruncle are congested and thickened, while that of the upper lid and bulb generally has a lesser degree of inflammation. As the disease becomes more chronic the symptoms subside, so there may be only variable degrees of thickening and congestion of the lower palpebral conjunctiva, fornix and caruncle. Discharge may be very scanty and noticeable only on arising. The lid margins may show variable degrees of redness or scaliness. Often the only symptom may be the inability to use the eyes for close work for any length of time.

Catarrhal ulcers which may occur during the course of the disease are often stubborn and have tendencies to recur. Many of them are corneal infiltrates which do not break down to actual ulceration. They are marginal almost without exception and have a tendency to become confluent. Perforations probably do not occur in pure staphylococcic infections.

The diagnosis is usually suspected by the clinical course, but should be verified by smear and culture. In my own experiences, culture seems the most reliable, as many smears, especially during the chronic stages, will show no organisms. For the average clinician the serum agar seems the most practical medium to use. The staphylococcic colonies can be recognized grossly. Some idea of pathogenicity can be obtained by the roughness or smoothness of the colonies and the amount of pigment. In general, the more pigmented and the smoother the colony and the more hemolysis on blood agar, the more pathogenic the organism. On serum agar, colonies of Morax Axenfeld bacillus, which also causes catarrhal ulcers, may be recognized grossly by the

characteristic pitted appearance of the colonies due to liquefaction of the media. One must remember that staphylococci, especially staphylococcus albus, is a frequently normal inhabitant of the conjunctiva or may be a secondary invader or contaminator.

Treatment is varied and consists of the usual antiseptics, applications of 2 per cent silver nitrate to the conjunctival surfaces of the lids, massage of the lids to express the meibomian glands, and use of hot compresses. In occasional cases, 5 per cent silver nitrate produces results when 2 per cent fails.

Before the advent of sulfonamides, the use of staphylococcus toxoid and vaccine was the most satisfactory treatment for stubborn cases and still should be used in severe or refractory cases, because it will cause a generalized antibody response as well as desensitize the individual to the toxin. Staphylococcus antiserum has been used with some success, but the average case hardly warrants its use. Massage of the lids in conjunction with 3 per cent ammoniated mercury ointment was very helpful, although more recently the sulfathiazole powder and now the ointment in 5 per cent strength seem preferable. Many cases respond to this dramatically, others in lesser degree and some show no response at all. Some cases seem to show slower response to this drug during recurrences, indicating the ability of some strains to develop a tolerance to the drug. Rarely an individual may show a reaction to the drug with an exacerbation of symptoms, usually an increased inflammation of the conjunctivæ and lids, with lessened discharge. This condition improves rapidly when the drug is withheld. The sulfathiazole ointment should be used frequently, up to eight times daily, and should be accompanied by gentle massage of the lids in chronic cases. Severe cases and those that have a tendency to recur should be treated with the vaccine or toxoid in increasing doses to establish an antibody titer sufficient to cure or improve the disease. Those cases which occur during the course of styes or chalazions usually respond to treatment of the primary condition. The serobacterin preparation containing both the antigen and the antibody seems in my experience to be the preparation best suited for the treatment of severe cases, especially those complicated with keratitis or catarrhal ulcers. This preparation is marketed in the form of the combined serobacterins of several strains of staphylococci and streptococci. In milder cases the toxoid or vaccine is sufficient to build up an antibody titer and also has a foreign protein effect.

Those cases complicated by the superficial corneal epithelial defects, if painful, may be treated by closing the eye with a patch, provided the discharge is scanty and the pad is removed frequently for treatment with hot applications, cleansing and instillation of antiseptic or sulfathiazole ointment.

Cases of catarrhal ulcer are treated as for severe uncomplicated staphylococcic conjunctivitis. In addition the ulcers should be cauterized with trichloracetic acid or other strong antiseptic, using Gifford's corneal probe with a wisp of cotton which is sparingly dipped into the acid. Atropine or other mydriatic is instilled when indicated and can be prescribed in a cod liver base which supplies the benefits of vitamin A locally.

Bacteriophage has been used with some success. It may cause an exacerbation of symptoms during the first day of use. My own limited experience with it did not warrant its use in preference to the sulfathiazole or toxoid.

Scobee in a series of eighteen cases of recurrent staphylococcic conjunctivitis had secured improvement in all cases using 1 to 5,000 aqueous solution of zephiran, four times daily and weekly massage of the meibomian glands.

Julianelle, Boots and Harrison, using toxoid as sole treatment in thirty cases of staphylococcic eye infection, concluded that toxoid is not an effective method of treating presumably staphylococcic eye infections.

Only ten of their cases showed improvement during the treatment and thirteen cases were asymptomatic after six months.

Presumably, a sensible approach to the treatment of staphylococcic conjunctivitis is not any one remedy for all cases, but different treatment or that combination of treatment which seems most suitable for each case. The elimination of local foci as meibomitis or infection in pseudoglands of Henle are important. Massage of the lids is helpful, especially if used in conjunction with antiseptics or sulfathiazole ointment. Probably the value of toxoid is also increased if some of the stagnating pockets of staphylococci are expressed from these glands at the time the antibody titer is rising. It is possible that dental infection may act as a sensitizing factor to the

toxin in rare instances. The use of vitamin A has been claimed to cure some cases of asthenopia, and it is possible that some of these cases may have been mild cases of chronic conjunctivitis which benefited from the generally increased bodily resistance following the use of vitamin A.

I have selected twenty-one cases, which were sufficiently stubborn to warrant more than average study. Of these, seven were staphylococcus albus, the others were staphylococcus aureus or citreus. Eight of these patients had recurrences. Only five were bilateral, which is contrary to most findings. Three of these cases followed a definite history of foreign body, a few others gave indefinite histories of starting after dirt or dust had blown into the eyes. Two patients had styes, three had obvious lid margin infection, and three had infected glands of Henle, which could be considered as possible cause of the infection. Five of the cases had swelling or dermatitis of the lids. Three cases had low grade iritis, and seven of them had catarrhal ulcers. Only five patients were seen at the time of the superficial keratitis which is believed by Drs. Allen and O'Brien to occur at some time in all of them. Four of the patients had dental extractions during the course of the disease, which for some reason seemingly had a beneficial effect on the disease. All of these cases were treated with vaccines and sulfathiazole. The majority of them responded well. Eight were stubborn and required longer treatment. One patient had frequent recurrences, each of which was quickly controlled by a single injection of toxoid, which kept her symptom-free for a few months at a time. One patient who had many glands of Henle, many of which were calcified, had only a moderate improvement after several months' treatment.

Conclusion

Staphylococcic conjunctivitis is a stubborn variety of conjunctivitis ranging from the severe acute forms to almost unrecognizable mild types, having a tendency to recurrences and chronicity.

The diagnosis should be suspected from the history and clinical findings, although cultures are necessary for confirmation.

It is probably the most frequent cause of catarrhal ulcers.

The stubborn varieties resist the usual treatment of conjunctivitis. Sulfathiazole and the staphylococcic vaccines and toxoids are valuable aids in the treatment of these cases.

VISUAL MALINGERING

A. G. ATHENS, M.D.

Duluth, Minnesota

VISUAL malingering may be briefly defined as the assumption, by an individual, of a false visual status and the attempt to convince others of this status for purposes of gain.

The malingerer may simulate loss of vision where there is none or he may magnify an existing visual impairment. Occasionally one may find it advantageous to simulate better vision than he actually has. Such an individual is usually concerned with holding his position, in acquiring a new position or in gaining entrance to the armed forces, when knowledge of his actual visual acuity would thwart him. With such individuals one may generally sympathize.

As to the frequency of malingering there is much disagreement. Neuropsychiatrists are inclined to assume the existence of an organic basis for most claims of injury. There are even those who contend that there is always an organic or psychopathological basis for simulation. We may appreciate the difficulty in detecting a malingerer who, for example, complains of pain in his back. Fortunately the occulist is in a position to prove malingering beyond any doubt and one who sees many industrial eye injuries is soon convinced that visual malingering is not rare.

Presented in Symposium on Eye, Ear, Nose and Throat Diseases at the annual meeting of the Minnesota Medical Association at Duluth, Minnesota, July 1, 1942.

The fact that most industrial employes are insured against accident probably contributes to the frequency with which false claims are made. Many an individual who would not consider taking action against his employer would not hesitate to sue for excessive damages, even on false claims of injury, when he realizes that an insurance company must pay the claim.

A further factor contributing to malingering is undoubtedly the readiness of a certain few lawyers to accept cases and prosecute claims for damage based on the flimsiest of evidence. It is unfortunate that an occasional member of our own profession will, perhaps unwittingly, play into the hands and serve the purposes of such lawyers and their clients.

It is not dishonorable and is perfectly ethical for a physician to examine a client and even to appear in court for any properly qualified attorney, however notorious he may be, provided the physician is convinced of the honesty of the claims supported. However, I believe the physician should establish certain principles for his guidance. He should see that both the attorney and his client understand that his examination is made for the sole purpose of obtaining the facts and that his reports or any court testimony will be based on such facts. In other words, that he is not entering a partnership with an attorney for the purpose of winning a case. It is apparently sometimes difficult for an attorney to grasp this mental attitude on the part of a physician. Furthermore, I believe that no physician should obligate himself to examine a client and testify on his behalf on a contingent fee basis, for in so doing he compromises his report or testimony from the start. Such requests are not liable to come from highly reputable attorneys.

A physician who accepts medico-legal cases is generally asked to make a report, with his opinion as to the amount of disability and its relationship to an accident, to an attorney, either one who is the agent of an insurance company or of the individual who is making claim for compensation. He furthermore is liable to be asked to go into court by the attorney who requests the examination. If he is required to appear in court it will mean sacrifice of valuable time from his practice and often at the most inconvenient times. He should therefore charge a fee sufficient to properly compensate him for his time and work. He can then ungrudgingly devote adequate time and effort to the case.

One should never half-heartedly enter such work. He should be able to make positive statements of facts as he finds them. His reports should be concise, but complete and in simple terms. He should never be induced to go into court half prepared in a case. There are few scenes more pathetic than an honest, capable physician being made ridiculous on the witness stand by a smart lawyer, simply because he has not properly prepared his material. Such a physician not only humiliates himself but he is often of little or no value as a witness or may even do harm to a worthy litigant. His poor showing also reflects on the entire medical profession.

One must distinguish between the malingerer and the hysteric. This is not always easy but can usually be done by the attitude of the individual. The difference is in the state of mind. It has been said that the hysteric suffers from a psychic abnormality, while the malingerer suffers from a moral abnormality. The hysteric believes that he can't see but desires good vision and is anxious to coöperate with the examiner. The malingerer knows that he can see but tries to mislead and deceive the examiner. He is often sulky, uncoöperative and, at times, even hostile toward the doctor.

It has rightly been said that the physician is an enemy of the malingerer. He stands between the malingerer and his selfish ends. The physician should not, however, let any hastily acquired opinion interfere with a fair and impartial examination. But once he is convinced of malingering there is nothing gained by coddling or trying to keep the good will of a faker.

Presented with an individual claiming visual loss, one should first take a careful and detailed history of the alleged accident or injury. This should give an approximate picture of the eyes prior to the accident. Exactly what happened at the time of the accident? Was he rendered unconscious by a blow or a fall? Were there cuts or bruises on or about the eyes? Was visual loss immediate or was it noted after weeks or months had elapsed? If, for example, he volunteers that he was formerly considered a good marksman, using his injured eye, but since the accident has had poor luck at shooting, some substance is given to his claim. Whereas if he merely insists

that his eyes were perfect prior to an accident, which may have consisted of injury to some remote part, that he did not request or receive immediate treatment to his eyes, but that some weeks later he noted poor vision, one is far from convinced.

A complete detailed examination of the eyes should be made. This should include refraction, extraocular muscle balance, visual fields, and x-ray if penetration of the globe is at all likely. Measures for determining the state of general health, such as blood pressure reading and urinalysis should be taken if indicated. Visual tests should be left until the last. The size and motility of the pupils should be observed. An eye that reacts to light stimulus can hardly be totally blind. Dilated pupils that fail to react to light or in convergence may be the result of a mydriatic. The individual should be kept under observation for a week or ten days to see if a mydriatic has been used. If only one eye shows a fixed pupil, stimulate the retina with a small beam of light and watch the pupil of the other eye. The presence of the consensual reflex is proof that the stimulated eye is not blind. Mydriasis with a fixed pupil is said to occur rarely in hysteria. A blind eye, if screened, may deviate outward as the good eye fixes.

If a total or even a high degree of blindness is claimed in one eye place a 10 to 20 degree prism base out before the injured eye and ask the individual to fix a small light at the reading distance. If the eye turns in to take up fixation, malingering is proven (von Welz). A blind eye does not fix. Binocular single vision must be present in this test.

Bruner suggests the trick of holding up the subject's hand with all but two fingers flexed and, with his good eye closed, asking him to state the number of fingers extended. The truly blind will invariably answer correctly, while the malingerer will frequently answer falsely.

One who assumes better vision than he actually has is liable to memorize the usual charts and so be able to deceive the examiner. A homemade chart with an entirely different arrangement of the letters or the broken G or E letters may be used to obviate this possibility.

Those claiming partial blindness in one eye constitute the great majority who seek compensation for visual loss. For detecting these, numerous tests have been devised. These consist largely of colored letters viewed through colored glass or the use of spheres, cylinders and prisms manipulated in ways to confuse the subject and induce him to read the test letters with his injured eye in the belief that he is reading them with his uninjured eye. These will be discussed in groups and no attempt will be made to describe in detail each individual one. Many are mere modifications of earlier tests. It is not necessary that the examiner be acquainted with all or even a great number of the various tests. He should thoroughly familiarize himself with one or two tests in each group, involving different principles, and be able to use and interpret these without any hesitation.

One trick commonly used by experienced malingerers is that of closing the injured eye during a test in order to determine which eye he is using. Walker suggests that this be overcome by the examiner resting his thumb against the superior orbital rim and gently drawing upward on the upper lid, which renders closing impossible.

A commonly used test is to fog the vision in the good eye with a strong plus sphere while a very weak or plano lens is placed before the injured eye. If the subject reads thus he is doing so with his injured eye. Bruner suggests, in a young person with one normal eye, placing a +3.00 D sphere before his good eye and having him read the near card at 8 inches. Then he unobtrusively removes the card to 12 inches. If reading is still possible, it is with the injured eye, as the card is now beyond the focal point of this lens.

Many tests involve the use of cylinders in the trial frame. Jackson's crossed cylinders test is probably the best known of these. He places a +1.00 D cylinder and a —1.00 D cylinder in the trial frame, with their axes coinciding, before the good eye. A plano lens is then placed before the injured eye. The subject is then told to read the chart and while he reads, one cylinder is turned until the axes are perpendicular. In this position the resulting crossed cylinder is slowly rotated. If he continues reading, he must be doing so with his injured eye, as the vision in his good eye is blurred by the crossed cylinder. There are various modifications of this test. Since the introduction of polaroid glass, Gradle has devised a test making use of the fact that when two discs of this glass are placed so that the direction of their polarization crosses at right angles, very

little light is admitted. The discs are rotated before the good eye much as are the cylinders in Jackson's test.

Numerous tests make use of prisms. One of the best of these was introduced by Duane. He asked the subject to read aloud small Jaeger type and while he was so doing a 6 degree prism base up or down was placed before his injured eye. If he could see the print with the injured eye the resulting diplopia rendered further reading impossible. A better test, which I have often used in a modified form, but only recently learned, was described by Dr. Todd; it makes use of a double prism. Two prisms of about 5 degrees are placed bases together in a disc which fits into a trial frame. This disc is placed before the good eye with base line of the prisms at axis 180 so that this line bisects the pupil. The smallest line on the Snellen chart which the subject has been able to read with the good eye, or the line which you judge he should read with the injured eye, is now illuminated. He is then told, "Now this special glass multiplies this line. Instead of one line, you see three lines each above the other." When he admits this, he is again told, "Now with your good eye read the middle line." If he does he is caught. The prisms produce two lines with the good eye, one displaced above and one below the normal level. The third line between these, at the normal level, is seen by the injured eye. This test has the advantage of determining the visual acuity as well as detecting simulation.

The principle of the bar test is employed in various ways. In its simplest form the subject is asked to read Jaeger type and while reading, a pencil or rule is held vertically midway between his eyes and the page. If he continues reading, he is doing so with both eyes, as the pencil obscures a portion of the print from either eye.

Snellen's red glass test is based on the principle that colored light rays can pass through glass of the same color, but not through glass of a complimentary color. Letters in red and green glass, illuminated from behind, are viewed through discs of red and green glass placed before the two eyes. If he reads both colored letters he is reading with the two eyes as only the letters corresponding in color to the disc before the good eye can be seen with that eye. Care should be taken to see that the glass in the discs is exactly the same shade of color as that in the letters. Letters painted on cards are not as satisfactory because of the difficulty in matching the colors in the glass.

A number of tests have been described involving use of mirrors which reflect images of letters placed over the patient's head, in such a way that they can be seen only with one eye at a time. Most of these require special equipment.

Use of the stereoscope and the Worth amblyoscope have been suggested by a number of men. Dr. Todd was one of the first to see the possibilities of the latter instrument in testing for malingering. Gifford has had test letters and numbers printed on semi-transparent cards with the visual angles determined for the length of the amblyoscope tubes. These cards are inserted in the slots at the ends of the tubes and the tubes set at such an angle that the images are crossed, the image of the letters in the right tube being projected to the left side and vice versa. The letters are illuminated by a light held at the ends of the tubes. The subject is then told to look into the instrument and first read the letters he sees with his good eye. If he is malingering, he naturally reads the letters which appear to be on the side of the uninjured eye. These are of course seen with the supposedly blind eye. This is the most reliable test which I have used. One cagey subject, who by blinking his supposedly bad eye, caught on to the maneuver, was trapped a moment later by my changing the type and while so doing shifting the tubes so that the images were no longer crossed. He then read the type appearing on the side opposite his good eye.

Occasionally one encounters an individual who claims partial loss of vision in both eyes. In such a case, by varying the distance of the chart from the eye, thus changing the visual angle, one may be able to detect simulation. A subject who is very observing may detect this deception, however. For such cases the author has had an ordinary Snellen chart reduced by a series of photographs in such a way that the visual angle of a line of letters on each reduction is the same as that of the next line above in the foregoing chart. For example, the top line representing 20/200 vision on the original chart represents 20/150 on the second, 20/70 on the third and 20/50 on the fourth chart. If the patient contends that he sees only the top line, representing 20/200, on the original chart, the examiner takes the patient into another room and pretends to "treat" the eyes to see if the vision can be improved. While so

engaged, his assistant replaces the original chart with the first one in the reduced series. The patient then is brought back to see if he can do better. If he still reads the top line he is caught, as this now represents a smaller visual angle. The procedure is repeated as long as he will admit seeing the top line. These charts should be hung on a background of plain white, as any contrast with the white card may reveal the decrease in size. It is contemplated to have these reduced letters printed on cards all the same size with the lines spaced as in the original.

To summarize, a plea is made for careful and detailed preparation in medico-legal cases. It is felt that it is one of the duties of the ophthalmologist to do his utmost to expose the malingerer. In so doing, he will render a public service as well as enhance his own reputation.

A brief outline of the various types of malingering tests is given and special charts for the detection of simulated binocular vision loss are presented.

SPONTANEOUS PARALYSIS OF THE SEVENTH AND EIGHTH NERVES, WITH RECOVERY

ORIEN B. PATCH, M.D.
Duluth, Minnesota

MEDICAL literature of nearly half a century contains references to "rheumatic paralysis of the acoustic nerve," and several reports of that era note "combinations of rheumatic affections of the auditory nerve with facial paralysis."

I wish to report a case which, if it had been reported at the time the other few had been, would have been classed as a "rheumatic paralysis" rather than a neuritis, of the facial and auditory nerves.

Case Report

On the morning of November 12, 1940, Mrs. F. A. S. walked a mile and a half against a thirty-eight-mile-an-hour wind in a temperature of 14° F. Arriving home, she complained of tingling and burning of the right side of her face together with marked postauricular pain on the same side. The skin was not discolored. This pain left in forty-eight hours, only hyperesthesia of the area remaining.

Five days later she suddenly became dizzy, nauseated and unable to sit up without vomiting. Her physician, finding no signs of vestibular or intracranial disease, treated her as a gastrointestinal dysfunction.

Two days later, on November 21, 1940, she awoke with a complete facial paralysis on the offending side (right). Her vertigo and nausea had practically ceased. She felt as though her right auricle was "limp" and her external auditory meatus "numb."

Her physician found no deafness nor nystagmus; the urine was normal; the blood pressure 120/80. Postauricular hyperesthesia was still present on the right but no hyperacusis was noted. During the next two weeks her facial paralysis cleared slowly beginning with ability to close her right eye better. She consulted her physician by telephone, during this time, reporting her progress day by day.

On the morning of December 9, 1940, she called her physician again and discovered to her consternation that she was totally deaf in her right ear. She habitually used her right ear during conversation, although she was right handed. I saw her the following morning in consultation.

The patient was a forty-nine-year-old white female, well developed and well nourished, not acutely ill. Her family history and past history were irrelevant except for occasional variations in blood pressure. Her record at the Clinic over thirteen years showed only an occasional gastrointestinal upset. Her laboratory findings on this examination showed a negative Kline, hemoglobin 82 per cent, erythrocytes 4.2 million, leukocytes 7,700, and the urine negative.

The only positive neurological findings were confined to the right side of the face and the right ear.

The face showed a slight weakness of the corner of the mouth on the right, and the right ala did not dilate well. There were no bite marks on the cheek. Taste was unimpaired.

The nose, throat and sinuses were normal.

The rest of the examination dealt with the ears. Both membrana tympani were normal in appearance, all landmarks being clearly visible. The eustachian orifices were patent.

Forks (C_1, C_2, C_3) were used to determine her reaction to the Schwabach, Rinné, and Weber tests. Air and bone conduction were lost completely on the involved side. Gellé test gave no response. Audiograms taken on the Maico Audiometer with and without masking were identical. The left ear showed essentially normal hearing up to 11,584 d.v. where there was a drop of 25 decibels, considered physiologic for her age.

Vestibular tests, using the Kobrak method, showed

From the department of Ophthalmology and Otolaryngology, The Duluth Clinic, Duluth, Minnesota. Presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

a markedly hypoactive labyrinth on the right; nystagmus coming on 45 seconds after 5 c.c. of water at 55° F. had been injected against the posterior superior quadrant of the drum. The nystagmus was rotary to the left and past pointing to the right was questionable. Inclining the head back 60° gave the same response except the nystagmus was horizontal. A trial frame with 20 spheres as lenses was used to detect the nystagmus, since it was so small and lasted only 20 seconds.

Caloric tests done on the left ear, same method, gave marked response with nystagmus coming on in 20 seconds and lasting 75 seconds with past pointing to the left with each hand about 6 inches, accompanied by a sensation of turning to the right and a marked tendency to fall to the left.

The impression at this time was that she had neuritis of the VII N. distal to the geniculate ganglion with secondary involvement of both branches of the VIII N.

She was given thiamine chloride 0/009 gm. orally, four times a day. No other therapy was used.

She returned three weeks later saying she had "about 7/8" of her hearing back in the right ear. For the preceding ten days she noticed a "strange metallic rustle in the deaf ear." Further, she stated spontaneously, "As soon as I noticed that rustle in my ear, I found I had a little of my hearing back; since I could make out fairly well on the telephone with it." Examination this time showed no evidence of facial paralysis. Hearing tests showed decreased bone conduction on the right, Rinné negative, Weber to the left. Tragus test was not done.

An audiogram showed an average loss of 25 decibels up to 2,048 div. with a sharp drop of 45 decibels af- 4096 d.v. and 60 decibels loss at 11,584 d.v. The left ear was masked. Hearing in the left ear remained essentially the same. She was told to reduce the thiamine chloride to 0/009 once a day.

She returned again three months later, by request, and her response to forks was equal on both sides. The audiogram showed the right ear now to be slightly better than the left, but due to the fact that she came in at an unusual hour, there was about ten decibels of noise in the room, which may account for the decrease in acuity. All other tests were done with absolute silence in the room.

Exactly one year later (March 12, 1942) she returned and her hearing was rechecked. The only significant features then were: (1) increased dip at 4096; (2) slight increase in loss of high tones. She had been in excellent health during the past twelve months. Both of these points may be explained by the normal physiological loss of hearing due to advancing age, as shown by the slide.

Comment

Politzer in his text "Diseases of the Ear" pointed out that this condition, ". . . if judged from its clinical cause, is most likely brought about by a neuritis." Bing in 1880 reported a case in which the auditory apparatus was affected alone. Hong and Morpurgo, Moos, Rosenbach and V. Frankl-Hochwart reported combinations of "rheumatic affections of the auditory nerve with facial paralysis between 1880 and 1897.

Gradenigs, Barnick and Lannois in 1890 demonstrated that the paralysis of the sound-perceiving apparatus may be considered as a neuritis of the acoustic nerve, and took their cases from patients suffering from influenza.

Of interest in this case presented, Mrs. F. A. S., is the fact that it follows so closely the keenly observed clinical course described by many of the early investigators. One point will demonstrate this, and I quote again from Politzer: "The course of this disease is such that the vestibular symptoms disappear first, while the disturbance of hearing returns to its normal condition only at a later stage. In a number of cases, a permanent disturbance of hearing remains."

Conclusion

A case has been presented in which paralysis of the VII and VIII nerves was brought about, in the order of (a) vestibular portion of VIII first, (b) VII second and (c) cochlear division of VIII lastly. There was a complete recovery. The geniculate ganglion was spared.

MENINGITIS INCREASES ALMOST 20 PER CENT IN WEEK

Cases of meningitis throughout the nation increased almost 20 per cent during the week ending January 23, latest for which figures are available. Reports from state health officers to the U. S. Public Health Service show 354 cases for the past week as compared with 298 for the week of January 16. Most of the cases are on the East and West coasts.

Total number of cases for the year to date, that is, to January 23, is 941, which is probably the largest number for that short a period since the U. S. Public Health Service has been keeping weekly records of this disease.

Influenza cases totalled 4,387 for the week of January 23, about the same as for the previous week. Measles increased slightly.

There were 23 cases of smallpox, five in Ohio and four in Indiana. No other state reported more than two.—*Science News Letter*, February 6, 1943.

LOSS OF CILIA IN THE RESPIRATORY TRACT AND ITS RELATION TO DEATH FROM RESPIRATORY DISEASE

Preliminary Report

A. C. HILDING, M.D.
Duluth, Minnesota

SOMETIMES rather obvious pathological changes escape attention for a long time, probably because their relation to known facts is not appreciated. Perhaps it is because they are not needed to explain the current theories concerning the conditions in question. There are very striking pathological changes in the respiratory epithelium of the bronchial tree in asthma and other respiratory diseases which have either escaped attention entirely or have been insufficiently emphasized. The object of this study is to point out some of these changes, especially those involving the loss of cilia.

The material thus far studied consists of the tissue sections from thirty-one fatal cases of asthma, twelve fatal cases of influenza, and six fatal cases of bronchopneumonia, found in the files of the Department of Pathology at the University of Minnesota.

Asthma

When death occurs in status asthmaticus the bronchial tree fills up with a heavy, tenacious, mucinous secretion. Death is due to asphyxia. The usual explanation given is that the secretion is too heavy for the respiratory tract to remove.

Normally, the tract is kept open and free of accumulated secretion and debris by means of ciliary action. There is a continuous thin blanket of tenacious mucus normally covering all of the epithelial surfaces. This blanket is in constant motion, being propelled by ciliary action, and is removed and renewed two or three times each hour. I once made some tests designed to determine what type of secretion was best handled by the ciliary system.[2] Three types of material were tested, namely, thin aqueous solutions, thick pus-like material, and gummy tenacious material prepared from commercial mucin. It was found that a very heavy, tenacious mucin, so gummy that it could be picked up with thumb forceps, was moved up vertical surfaces by ciliary action with the greatest dispatch and the most cleanly.

The results of these tests do not agree with the theory that secretion accumulates in the respiratory tract in asthma because it is too heavy for the epithelium to remove. There is another explanation which was found in this pathological material. A metamorphosis of the respiratory epithelium had taken place in a large proportion of the cases. The usual ciliated columnar epithelium had been replaced by epithelium com-

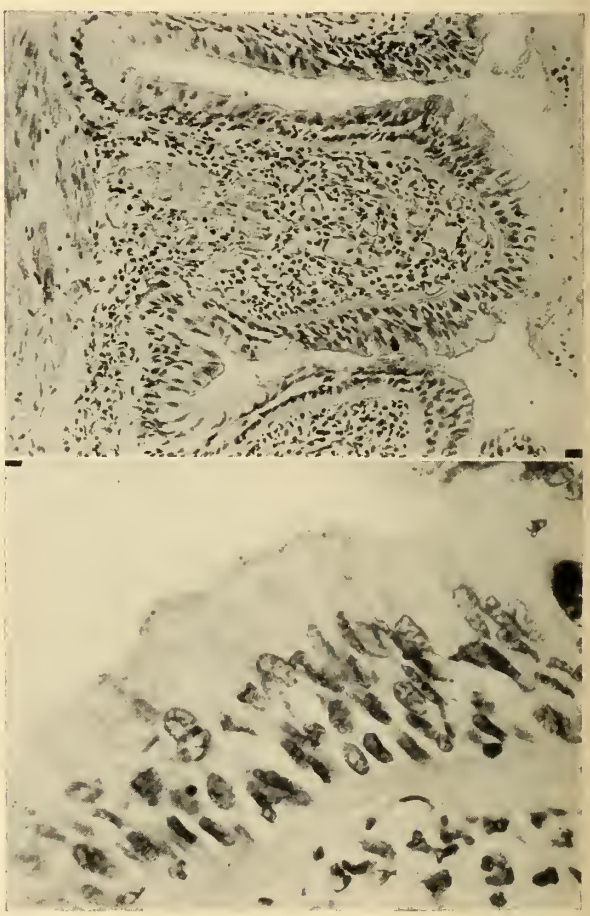

Fig. 1. Low power and high power views of the bronchiolar epithelium from a fatal case of asthma of six years' duration. Practically all of the cells are non-ciliated secreting cells instead of the ciliated cells normally found in this epithelium.

From Department of Pathology, University of Minnesota. Presented before the Milwaukee Oto-Ophthalmic Society March 11, 1942, the Society of Experimental Biology and Medicine March 18, 1942, and the Minnesota State Medical Association July 1, 1942.

posed largely, or entirely, of goblet cells or secreting cells (Fig. 1). This change is mentioned by Bell in his textbook,[1] but I have found no other reference to it.

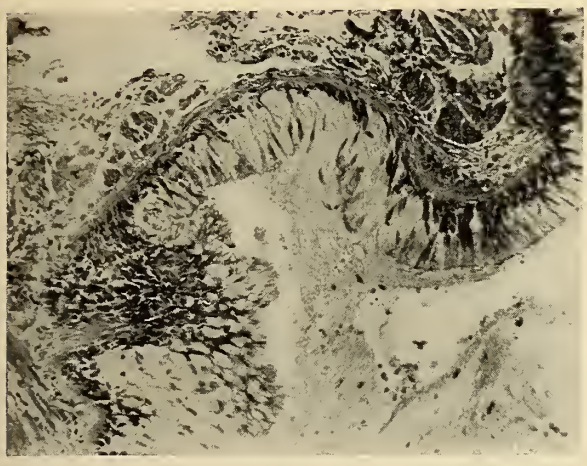

Fig. 2. Bronchiolar epithelium from a fifty-year-old patient with a history of long standing asthma. Note how the mucus produced by the epithelium remains attached deep in the epithelium and still is fused with the mass in the lumen.

Fig. 3. Low power and high power views of bronchial epithelium in a fatal case of asthma of twenty years' duration. The entire epithelium is melting into the secretion accumulated in the lumen. There are no ciliated cells whatever in this area.

A study of the lung sections in the thirty-one cases soon showed that clinical asthma is not a disease entity. A variety of pathological pictures were found. Thirteen showed the metamorphosis mentioned with little or no inflammatory reaction. Six had pneumonia with purulent bronchitis. Three showed marked constriction of the bronchioles with no other marked change. (In one of these the final pathological diagnosis read, "Cause of death not determined.") Four exhibited extensive sloughing of the epithelium as the chief change. In two the epithelium appeared to be essentially normal, and of the remaining two one had pneumonia with little change in the bronchial epithelium, and the other was a case of acute tracheo-bronchitis.

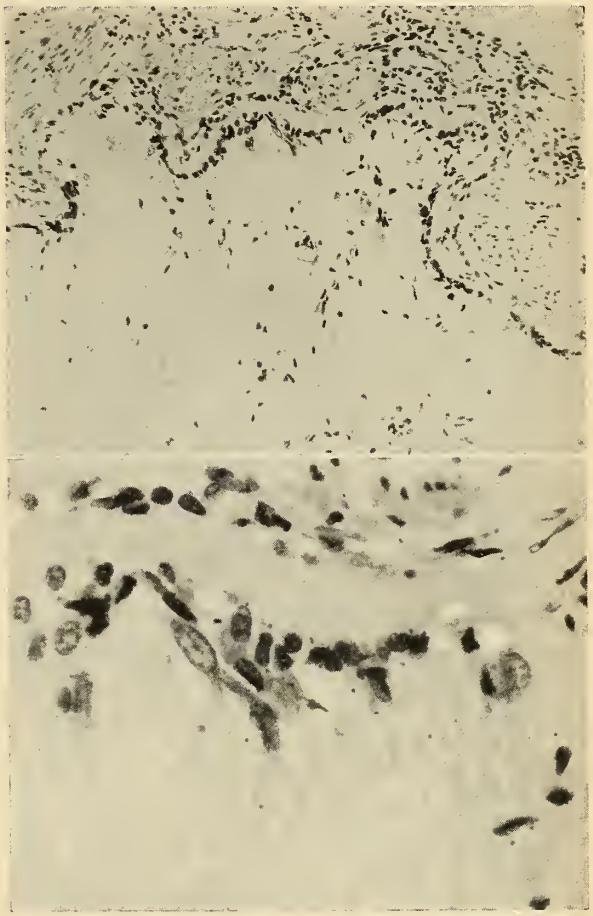

Fig. 4. From the same case as Figure 3. Photomicrograph of another area of bronchial epithelium. Here some ciliated cells have been preserved. The mucus in the lumen appears to be free over the cilia but is attached to the epithelium in the secreting cells. This area suggests that the individual ciliated cells may actually become secreting cells. The different appearances of the individual cells might be different stages in the metamorphosis.

The metamorphosis of epithelium found in the largest group (the 13) seemed to occur in those cases which were not infectious or complicated by infection. A very great increase in the number of goblet cells was found. It ranged from 30 per cent to as high as 100 per cent in some areas (Fig. 1). These secreting cells were all devoid of cilia and seemed to be actively engaged in secreting the material with which the lumina of the bronchioles were more or less completely filled. In many areas the secretion produced by

the cells did not leave the cells completely, but nevertheless fused with the accumulated mass lying in the lumen (Fig. 2). Thus the mass was anchored deep within the epithelium. In some areas the entire epithelium appeared to melt into the accumulated secretion, even the nuclei passing out into the lumen (Fig. 3). Here and there areas were found containing alternating patches of ciliated cells and secreting cells. The accumulated secretion in these areas appeared to be free of the epithelium over the cilia, but attached where there were no cilia (Fig. 4).

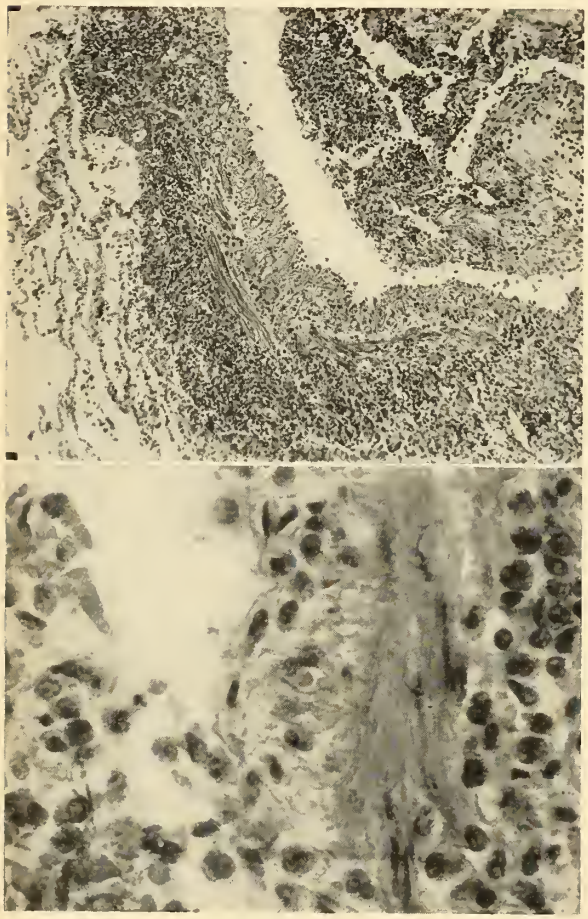

Fig. 5. Low power and high power photomicrographs of the bronchiolar epithelium from a fatal case of acute tracheo-bronchitis. There is an extensive severe purulent inflammation with radical changes in the epithelium. No ciliated cells could be found.

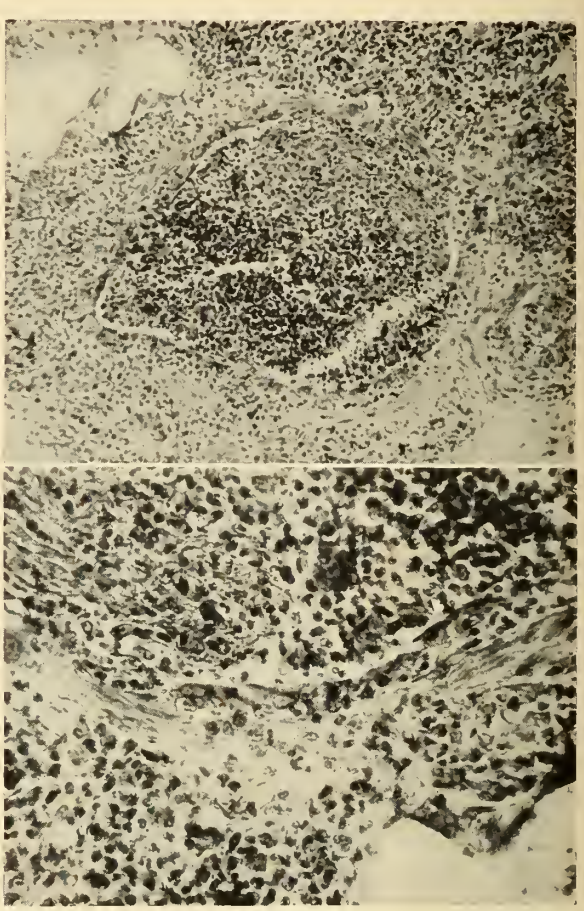

Fig. 6. Low power and high power photomicrographs of a bronchiole from a fatal case of influenza from the pandemic of 1918. The epithelium is entirely destroyed, and the lumen is filled with a purulent secretion.

Tracheo-Bronchitis

One of the cases listed among the asthmatics proved to be a case of acute tracheo-bronchitis. He gave no history of having had asthma previous to his final illness. His final illness lasted only three days and began like an attack of the common cold. His chest was clear until the final day when he became dyspneic and asthmatic sounds were heard in his chest. He was hospitalized and given oxygen and adrenalin, pantopon and atropin, but died with extreme dyspnea. In the necropsy report the heart was described as normal. "The lungs were heavy, crepitated throughout and exuded abundant fluid on section. There were numerous thick tenacious plugs expressed from the bronchioles of both lungs."

The microscopic sections reveal almost complete destruction of the bronchial epithelium (Fig. 5). The cells in many cases had been exfoliated down to the last layer of stellate cells. Not a single intact ciliated cell could be found. There was a beginning pneumonia, but the essential picture was that of an acute purulent

bronchitis with loss of respiratory ciliated epithelium and with all of the bronchioles filled with purulent exudate.

Influenza

The twelve cases of influenza were taken from the 1918 files. These patients were among the many that perished in the pandemic of 1918. The histories indicated that the patients died deaths which were currently described as "drowning in their own secretions."

There were only a few lung sections saved from each case, and most of these were taken near the periphery. Some bronchioles were found in each, however. The essential picture in these sections was that of an acute bronchitis with beginning pneumonia. The bronchioles were filled with exudate, and the epithelium was very badly damaged (Fig. 6). In two the epithelium was destroyed to the last cell as far as could be determined. In seven it was largely gone, and in two partially gone. In only one was the epithelium fairly intact, and in this one the surface cells were so generally exfoliated that only a few cilia could be found.

Discussion

In the asthmatic cases which were uncomplicated by infection, the essential cause of death seemed to be failure of the ciliary system. The thick, gummy secretion which causes the asphyxia is of the type of material which cilia handle best. The failure of the ciliary system is due to a progressive metamorphosis or replacement of the ciliated, columnar cells by secreting or goblet cells which are non-ciliated. Accumulation of quantities of this mucinous secretion in the bronchial tree is favored by three factors: (1) loss of cilia to move it; (2) increased production of mucus by the increased number of secreting cells; and (3) attachment of the mucinous mass to the cells which produce it.

Whether the change from ciliated to secreting cells is an actual metamorphosis of the individual cells from one type to another, or whether it is a replacement of one type of cell by another type, has not been determined, and is not essential for this discussion. (Figure 4 suggests that it may be a true metamorphosis.) Neither has the cause of this change been determined, but there is some experimental evidence to indicate that it is due to decreased volume of air flow. I have produced this change experimentally in the nose of the rabbit.[3]

Death in the single case of tracheo-bronchitis seemed to have been due to asphyxia from accumulated secretion. The loss of ciliary action here also was probably the immediate cause of death.

The clinical course and the pathologic picture in the bronchioles in the influenza cases is suggestive of the pathology of the common cold.[4] The ciliated surface cells in the nasal epithelium are largely sloughed away by the second day of a severe cold. The secretion is abundant and very liquid, but it does not accumulate. Instead it drains away harmlessly by gravity through the nostrils or choanæ or is blown out. After three or four days the ciliated cells which were lost have again been replaced, and the ciliary system is again functioning. If such an extensive loss of cilia takes place in the bronchial tree in the early stages of influenza, it is likely that the accumulation of abundant watery excretion in the air passages is due at least partly to this cause. That the cilia are lost is clear; at what stage the loss occurs is not known. If loss of cilia be the cause of the accumulation of the serous fluid which "drowns" the patient, then it may also be the cause of the extension of the infection into the alveoli and of the development of pneumonia. It is fair at this stage of the study to state that loss of ciliary function is at least an important factor in the development of influenzal and other pneumonias. The ciliated epithelium was badly damaged in the cases of bronchopneumonia examined. It is common knowledge that cilia are lost in many areas in cases of bronchiectasis. Probably loss of cilia is a factor also in development and distribution of bronchiectasis.

THE BENEFICIAL EFFECT OF UREA IN TOPICAL SULFONAMIDE THERAPY

I. Treatment of Infected Dermatoses. II. Effectiveness of Urea-Sulfonamide Combinations in Sulfonamide-Resistant Infections

ERNEST A. STRAKOSCH, M.D., M.S., and WILLIAM G. CLARK, Ph.D.
Minneapolis, Minnesota

DURING the past two years many reports have been made of the use of topically applied sulfonamides in the treatment of infected dermatoses, infected wounds, burns, ulcers, and so forth. A great number of workers in this field have used the same or different sulfonamides in various vehicles, reporting excellent results. The most successful results have been obtained in conditions in which the causative micro-organism was either a streptococcus or a staphylococcus, or in secondarily infected lesions. The subject is well reviewed in the new second edition of Spink's book on sulfonamides.[14]

Although the topical application of the sulfonamides proved to be definitely superior in the treatment of pyogenic skin conditions as compared with the older methods, it nevertheless often falls short of our expectations, and sometimes fails completely. This, among other reasons, has caused some workers to lose interest in the sulfonamides, turning to other possibilities such as the use of gramicidin, penicillin, and the like.

Our best results were obtained in very superficial pyogenic infections, such as impetigo contagiosa. In various chronic eczematoid lesions from which large numbers of streptococci or staphylococci were recovered, the effects of a 5 per cent sulfathiazole ointment were much less striking, as was also shown by Pillsbury et al.[11] Some of the failures observed in our clinics may be attributed to the improper selection of the ointment base. The value of such selection has been discussed in previous publications[16,17] In our work we have observed not only failure of the sulfonamides to benefit many cases, but an actual aggravation of the condition. It is our opinion that such observations will become more numerous, since there is hardly a skin lesion which has not been treated with these compounds in some form. Some of these aggravations are due to the use of the sodium salts of sulfathiazole and sulfadiazine, which will cause chemical burns even when used over a short period of time, due to the strong alkalinity of these salts (pH 9 to 10 in concentrations of 1 to 10 per cent).

In addition to the above objections, failures have also been observed even when the proper sulfonamides have been applied in the proper vehicles, or in powder form. These occurred in cases in which the skin lesions were either heavily crusted, or in which there was an abundance of necrotic tissue and pus. Since it is now well known that inhibitors of the sulfonamides, such as products of proteolysis in purulent exudates, are plentiful in infected wounds,[7] it would be very desirable to either: (a) find a method by which these inhibitors could be partially or completely removed or antagonized; (b) employ higher concentrations of completely dissolved sulfonamides which are non-caustic to open lesions; or (c) enhance the bacteriostatic action of the sulfonamides. Increased concentrations seemed not always to overcome the inhibitory effects of purulent lesions, as indicated by the results of some cases with 3 per cent sodium sulfathiazole and which did seem aggravated by this salt (see Table I). Higher concentrations could not be used because of caustic action. In this respect, it is admitted that higher concentrations of sodium sulfacetamide or of the calcium salts of sulfathiazole or sulfadiazine, which do not have such high alkalinities, might be effective. Another reason why failures have been seen in topical sulfonamide therapy, is possibly because the causative organisms were or became resistant to sulfonamides, the so-called "sulfonamide-fast" organisms.

Holder and MacKay[4] have recently reported that a powder consisting of urea 90 per cent, sulfanilamide 10 per cent, topically applied, markedly benefits contaminated and infected wounds. They point out that the strong urea mechanically removes sulfonamide inhibitors by its peptizing and hyperemic action. Strong urea increases the solubility of the sulfonamides,[5,13] and it also

Presented for publication, October 9, 1942.

cleans wounds by removal of necrotic tissue by its solvent action on such tissue. It is also bacteriolytic, deodorizes foul-smelling infections, and is very inexpensive. These qualities have been reviewed by Holder and MacKay in their several publications.[4]

We recently have been able to demonstrate that urea in low concentrations exerts a synergistic action with sulfonamides on Escherichia coli in a synthetic medium.[19] The same low concentration also neutralizes the sulfonamide inhibitory action of methionine and para-amino-benzoic acid, compounds which belong to the sulfonamide inhibitor group of compounds.[7] Since urea possesses the beneficial qualities pointed out above, it offers advantages over certain other substances, such as azochloramid, which has been shown by Neter[8] and others to neutralize sulfonamide inhibitor action, and enhance the bacteriostatic action of sulfonamides.

It would be highly important if an anti-sulfonamide-inhibitor or sulfonamide enhancing action could be clinically demonstrated for urea. Holder and MacKay's[4] cases indicate this possibility. We therefore attempted to compare, in suitable clinical cases, the local action of a sulfathiazole-urea mixture, with the action of sulfathiazole alone.

Experimental Studies

1. *Treatment of Infected Dermatoses.*—Twenty-eight cases of dermatoses due to staphylococci, streptococci, or both, were treated with a urea-sulfathiazole mixture. They were selected so that each case acted as its own control, presenting a bilateral involvement of the extremities or head. The comparison of the experimentally treated area with the control area was not always accurate, for it is difficult to find two equally involved areas. For better comparison of the action of the urea-sulfathiazole mixture as compared with sulfathiazole alone, the most involved area was always treated with the mixture. The mixture was applied in three ways. First it was applied in the form of an ointment consisting of sulfathiazole 5 per cent, urea 30 per cent, in a base consisting of fatty esters of diethanolamine mixed with petrolatum ("Hydrosorb," Abbott). The control ointment contained 5 per cent sulfathiazole alone. Secondly the mixture was applied in the form of wet packs of a solution consisting of two parts of water in which was suspended a powder mixture of urea 70 per cent, lactose 20 per cent, and sulfathiazole 10 per cent. The control wet packs contained saline saturated with sulfathiazole at 40°C. The solutions were shaken before use, as the sulfathiazole was present in excess amounts. Ten layers of gauze were used as packs, soaked with the solutions at least every hour. Sterile wax paper as the primary dressing prevents evaporation and reduces the amounts of solutions needed, as has been pointed out by Holder and MacKay.[4] Solubility determinations made by us and by others[5] have subsequently shown the concentration of the sulfathiazole in this mixture, saturated in water, to be of the order of 0.5 per cent; thus our powder mixture contained an unnecessary excess. These data for the solubilities of various sulfonamides in this mixture in various amounts of water, serum, and other solvents, will be published elsewhere. The lactose prevents crusting due to the tendency of urea to crystallize from a strong solution. It has also been used as a deodorant in the treatment of osteomyelitis and is claimed to make dressings less adherent, an observation which has been confirmed by us. It should be reiterated at this point that sulfathiazole is far more soluble in a strong urea solution than in water alone. Thirdly, the mixture was applied, as such, in powder form.

Table I shows the cases studied to date. The age, sex, involved areas, bacteriological findings, treatment, and healing time are listed. The healing time implies the time to complete epithelization of the lesions. Quantitative studies on suppression of the bacteriological populations cannot be made in clinical infections treated with bacteriostatic agents. Quantitative bacteriological studies in experimental animals with standardly infected wounds are being made at the present time and soon will be reported by us. The healing time and the appearance of the lesions as seen clinically in our hospital cases were therefore taken as criteria of the effects. Photographs illustrate the typical responses (Table I).

2. *Urea-sulfonamide Treatment of Pyodermic Lesions due to Sulfonamide-resistant Staphylococci.*—Vivino and Spink,[21] Tredway and Sadusk,[18] Helmholz,[3] Schmidt et al.,[12] Stokinger et al.,[15] and many others have shown that sulfonamide resistance can be acquired by staphylococci, pneumococci, streptococci, E. coli, and gonococci *in vitro,* and *in vivo* in patients treated with sulfonamides.

Neter[8,9] has recently reported that azochloramid can remove this resistance *in vitro,* as well as in two clinical cases, one of which was a wound infected with a sulfonamide-fast staphylococcus, and an empyema caused by a sulfonamide-fast streptococcus.

In a paper to be presented elsewhere[20] we have shown that sulfonamide resistance of various

strains of staphylococci recovered from sulfonamide treated patients, could be antagonized *in vitro* by concentrations of urea which did not effect the organisms in the absence of sulfonamides.

in vitro tests, which will be reported in detail elsewhere. We have been able to overcome this sulfonamide-fastness by topical treatment with urea-sulfonamide combinations where sulfonamides alone proved ineffective.

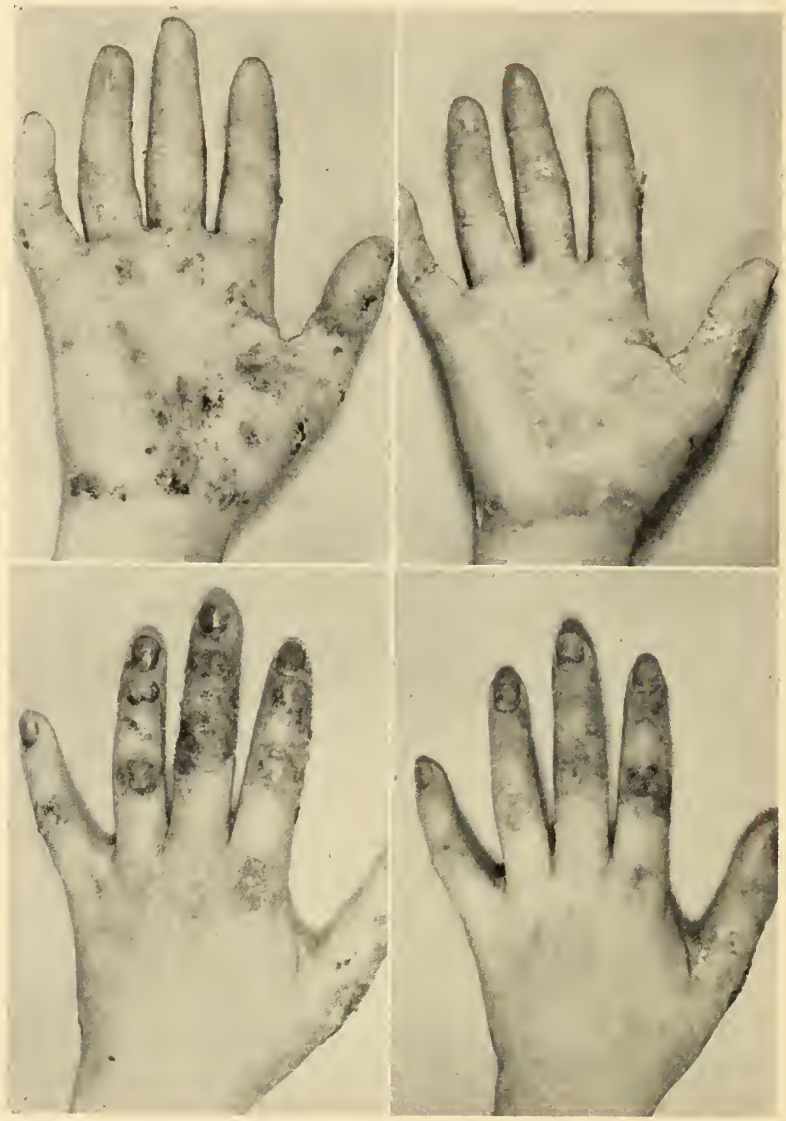

Fig. 1. (*upper left*) Case 27. Pyoderma, mixed infection. Right hand before treatment.

Fig. 2. (*upper right*) Case 27. Right hand after three and one-half days' application of urea-lactose-sulfathiazole wet packs.

Fig. 3. (*lower left*) Case 27. Left hand before treatment.

Fig. 4. (*lower right*) Case 27. Left hand after three and one-half days' application of 3 per cent sodium sulfathiazole wet packs. Still marked activity.

We have been fortunate in encountering two cases of wide-spread pyodermas the organisms of which were shown to be coagulase-positive, hemolytic *Staphylococcus aureus*, both of which were shown to be markedly sulfonamide-fast by

Case Reports

Case 1.—R. S., a four-year-old girl, was admitted on January 14, 1942, to the pediatrics service of the University Hospital, on account of an empyema in the right pleural cavity, which developed following pneumonia. During hospitalization, she developed, in March,

numerous furuncles which were unsuccessfully treated by oral and topical sulfonamide therapy. She was seen by us in consultation on June 19 for a crusted pyoderma involving the right buttock, thigh, and the right side of the chest. Topical sulfonamide therapy was again instituted but the lesions spread and resisted therapy. On July 15 cultures were shown to contain a sulfonamide-fast Staphylococcus aureus. On July 17 an ointment containing 40 per cent urea and 5 per cent sulfathiazole in Hydrosorb (Abbott) was applied and all the lesions were completely healed within six days.

Case 2.—M. R., a thirteen-year-old girl, was admitted to the dermatology service on May 7, 1942, for a large pyogenic granuloma involving two thirds of her left ring finger. The patient had an ulcerative colitis for some years and was in very poor condition. During her hospitalization, several hundred pyogenic lesions developed which eventually ulcerated on both legs, arms, and neck. Sulfathiazole was applied locally in form of powders, ointments, and wet packs, with no response. On July 22, the causative organism was shown to be a coagulase-positive, hemolytic, sulfonamide-fast *Staphylococcus aureus.* Since both legs were equally involved, we considered it an ideal test case to compare applied sulfathiazole alone on one side, with a urea-sulfathiazole mixture on the other. Saturated sulfathiazole in saline was applied to the left leg, and 40 per cent urea, 20 per cent lactose, 5 per cent sulfathiazole in water was applied to the lesions on the right leg as wet packs. Five days after the treatment was instituted, the urea treated side showed clean, pink granulation tissue, whereas the left side showed no change (Figs. 5 and 6).

Due to numerous complications, such as the patient's low resistance and her poor general condition, we were unable to obtain further beneficial effect with the strong urea therapy. This case will be reported in detail at a later date.

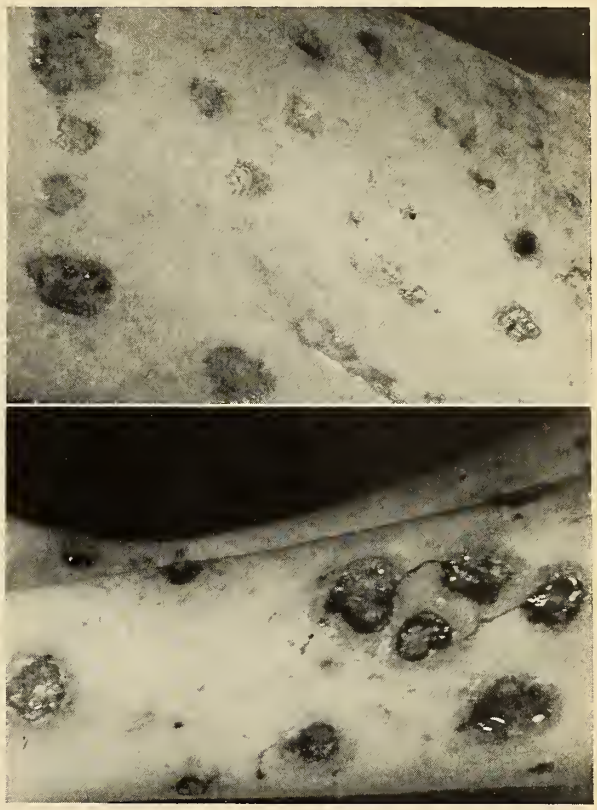

Fig. 5. (*above*) Case 2 (Part II). Lateral aspect of right leg after five days of urea-lactose-sulfathiazole wet packs application.
Fig. 6. (*below*) Case 2 (Part II). Left leg after five days of wet packs of saline solution saturated with sulfathiazole.

Discussion

Of the twenty-eight cases reported in part I, only five were not definitely benefited by the urea-sulfathiazole mixtures as compared with the sulfathiazole alone. One was a border-line case, and one was discontinued because of caustic action of the sodium salt of sulfathiazole, rendering the case uncontrolled.

We cannot explain the three definitely negative cases except to comment that the causative organisms may vary in their response to urea-sulfonamide therapy, under the clinical conditions present. A similar difficulty was experienced by Neter[9] who later recovered staphylococci after apparently successfully treating a wound infected with sulfonamide-fast staphylococci with azochloramid and sulfonamide.

The effect of urea in removing sulfonamide-fastness, is the first clinical report of this nature, other than Neter's preliminary abstract, in which an azochloramid-sulfonamide mixture was used. The importance of a method of combating sulfonamide-fastness will be, in our opinion, strongly emphasized in future applications of chemotherapy.

The advantages of urea in the treatment of infections, discussed in the introduction, should be reëmphasized at this point, namely—(1) its cleansing effect by removing necrotic tissue by lytic action; (2) it is bacteriolytic; (3) it deodorizes foul-smelling infections; (4) it stimulates granulation and vascularization;[1,2,4,10] (5) it is hyperemic; (6) it increases the solubilities of sulfonamides;[4,13] (7) it enhances sulfonamide bacteriostasis, antagonizes sulfonamide inhibitors and removes fastness of sulfonamide resistant organisms;[19,20] and last but not least (8) it is very inexpensive.

It must be pointed out that in our opinion strong urea therapy should be discontinued as soon as fresh, uninfected granulation tissue ap-

pears, since animal experiments on skin defects in rabbits,[10] guinea pigs,[2] the animal experiments of Brush and Conrad,[1] and the clinical experience published by Lange-Sundermann[6] in 1940 and confirmed by our observations have shown strong urea to be inflammatory. New granulation tissue which is contiguous with infected areas may be protected from continued urea treatment with ointment, as pointed out by Lange-Sundermann. Animal experiments have shown that strong urea suppresses epithelization and stimulates granulation in uninfected skin wounds.[1,2,10]

Summary

1. A strong urea-sulfathiazole mixture in wet packs, in ointments, and as a powder, has been compared with sulfathiazole alone in twenty-eight cases of bilaterally infected dermatoses, where sufathiazole alone was applied to one area and the mixture to the other area of the same patient. Urea-sulfonamide therapy gave much better results than sulfonamides alone.

2. Urea and sulfonamides topically applied in two cases of extensive pyodermas due to a sulfonamide-fast staphylococcus brought about successful therapeutic results.

3. The mechanism of the action of the urea-sulfonamide synergism is discussed.

We wish to thank Dr. H. M. Tsuchiya and Mr. D. J. Tenenberg for the bacteriological work; Doctor W. W. Spink for his coöperation and advice and Dr. I. McQuarrie for giving us permission to include case No. 1 (part II) in this report. We also wish to thank Miss H. F. Bruce for her brilliant coöperation in preparing various pharmaceuticals.

TREATMENT OF CRANIOCEREBRAL INJURIES IN MODERN WARFARE

GEORGE S. BAKER, M.D. and ALFRED W. ADSON, M.D.
Rochester, Minnesota

IN the present world war, as contrasted to the one of 1914-1918, changes in the type of explosives have produced changes in the type of craniocerebral injuries that are inflicted. It is estimated that in the first world war about 9 per cent of the wounds were caused by shells and about 90 per cent were caused by bullets. In modern warfare this ratio has been almost reversed. German high-explosive bombs are known to contain 90 per cent explosive material and only about 10 per cent of aluminum alloy casting, a type of construction which makes them very light for transportation by air. These bombs usually kill by the terrific blast they cause, rather than by projection of small fragments of their casings. However, these small fragments travel at an extremely high velocity and can cause dev-

astating damage to the soft parts of the body as well as to the skull and cerebral tissues. A small wound of entry through the skull may lead to extensive damage to the underlying portion of the brain; therefore, what seems to be a minor laceration of the scalp may, at a later time, prove to be a very serious craniocerebral injury.

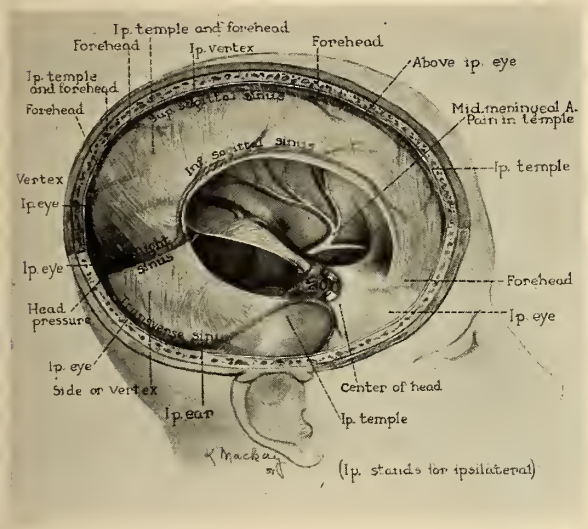

Fig. 1. Anatomic relationships of the falx and tentorium to the long processes of the skull.

General Considerations

In any consideration of damage to the skull and the soft parts within, the anatomic relationships of the brain and its coverings must be at least mentioned, so that the changes which may occur after cerebral injury can be interpreted. In Figure 1 are represented the anatomic relationships of the falx cerebri and the tentorium and its attachments to the bony processes of the skull. The middle meningeal artery is visualized in Figure 1. This artery often is the source of distress after fractures through the temporal area of the skull. The fibrous structures of the falx and dura in general are more or less fixed, and therefore any pressure which arises within the cranium will necessarily be resisted by the fixed tissues within the skull. The brain, therefore, will receive the major portion of the damage. A rapid increase in intracerebral pressure may shift the brain under the falx, with resulting unconsciousness of the person concerned. In severe trauma to the brain, notching of the cerebral peduncles by the tentorium also may occur; this usually results in spasmodic rigidity of the extremities in extension as well as various types of tremors of the extremities. When the increase in intracranial pressure is very slow, the brain is able to accommodate more or less for the pressure; hence the symptoms are not so marked as those of persons in whom this pressure increases very rapidly. Other anatomic changes which can be demonstrated are unilateral shifting of the brain, caused by the encroachment of a subdural hematoma as demonstrated in Figure 2*a*, and herniation of the cerebellar tonsils through the foramen magnum as in Figure 2*b*, which may follow spinal puncture carried out to control increased intracranial pressure or may follow spontaneously some sudden increase in intracranial pressure. This change may be accompanied by respiratory collapse or symptoms referable to the respiratory mechanism. Any of these anatomic variations of the pathologic changes may occur

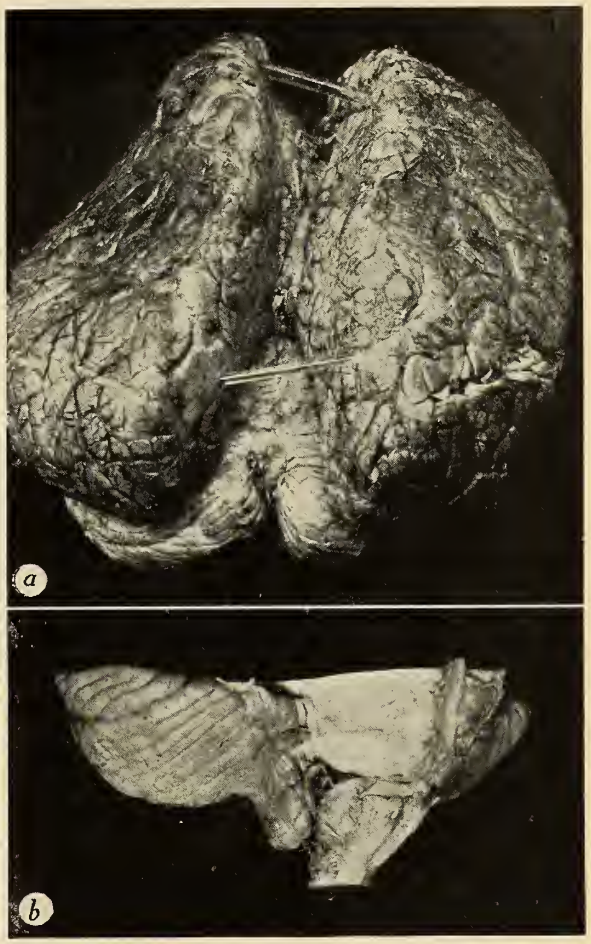

Fig. 2. *a*. Compression of the brain caused by a large subdural hematoma, showing shifting of the brain under the falx; *b*, herniation of the cerebellar tonsils through the foramen magnum, with compression of the medulla.

within the skull after injury. It is with those patients whose intracranial pressure shows a very rapid increase that we are most concerned in this discussion of war injuries to the craniocerebral tissues.

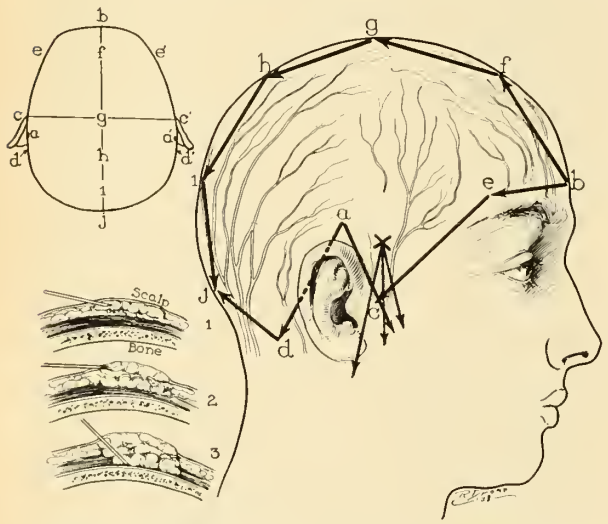

Fig. 3. Technique of the injection of the scalp by local infiltration (from Lundy).

Treatment

Primary Considerations. — The treatment of craniocerebral injuries is operative or nonoperative. When the surgeon is confronted with a craniocerebral injury during a military engagement, he must consider first the availability of proper materials and methods of treatment, and must by all means evaluate the severity of the injury. Under military conditions, it is advisable to treat the men who have received minor injuries first, so that they can return to their posts of duty. Severely injured patients can be cared for during a lull in activities. The physician who is to care for a patient suffering from severe craniocerebral injury must first evaluate the extent of the injuries to that patient in their entirety, and not merely from the standpoint of his specialty. Even though the damage to the brain and soft parts may appear to be very serious at the time, penetration of the abdomen with but a small fragment of shell may be much more serious, so far as the patient's life is concerned, than a cerebral injury itself. Therefore, the most serious injury must be treated first, and in the case of penetration of an abdominal viscus the wound of course should be sutured at once to avoid or overcome peritonitis; then the other injuries can be treated at a later time. It may be necessary to employ several surgical teams to expedite the proper treatment.

First Aid and Emergency Treatment.—In the outlying collecting stations which are adapted to the military needs of the advancing army, first aid and emergency treatment can be administered. It is therefore advisable that those rendering first aid treatment have an ample supply of powdered sulfanilamide and also first aid dressings by means of which chemotherapy can be instituted locally against all wounds. Superficial hemorrhage should be controlled and the patient should be carefully transported to the proper unit for treatment. The patient may be severely shocked because of loss of blood or exposure to cold; therefore, the treatment of shock is always a major problem during a military campaign. Oxygen can be administered by the mask method. Heat can be applied to the extremities by hot water bottles and blankets. Too much heat, however, may be detrimental. Loss of blood always can be replaced by the administration of plasma or the transfusion of whole blood, if donors are available. Sedative agents can be used, and in the case of craniocerebral injuries, barbiturates such as pentobarbital sodium, pentothal sodium, chloral hydrate and paraldehyde are to be recommended instead of morphine and its derivatives. After emergency treatment has been rendered and the shock has been controlled, a more detailed evaluation of the extent of the craniocerebral injury can be made by careful neurologic examination and by roentgenologic studies of the skull.

Nonoperative Treatment.—Not all craniocerebral injuries require operative treatment. Mild injuries with or without unconsciousness, linear fractures, small depressions of the skull, absence of lacerations of the scalp and of hemorrhage, ordinarily do not require a surgical procedure. The treatment of choice for such persons involves use of supportive measures such as fluids (2,000 c.c. per day) and control of pain by the administration of barbiturates, chloral hydrate or codeine. When a dehydrating program is indicated, a 10 per cent solution of glucose can be used intravenously, and magnesium sulfate can be given by mouth and by enema. Spinal punc-

ture has been debated greatly, both pro and con, with respect to its use in the treatment of craniocerebral injuries. In selected cases in which the initial pressure can be estimated by manometric methods and the spinal pressure can be lowered to only a half of the initial pressure, very few serious complications would be expected. The convalescent care will depend upon the extent of the injury and the manner in which healing takes place.

In Figure 4*a* and *b*, the roentgenograms disclose a compound comminuted fracture of the skull. Compound comminuted fractures of the skull perhaps comprise the most serious of all injuries sustained during a military engagement.

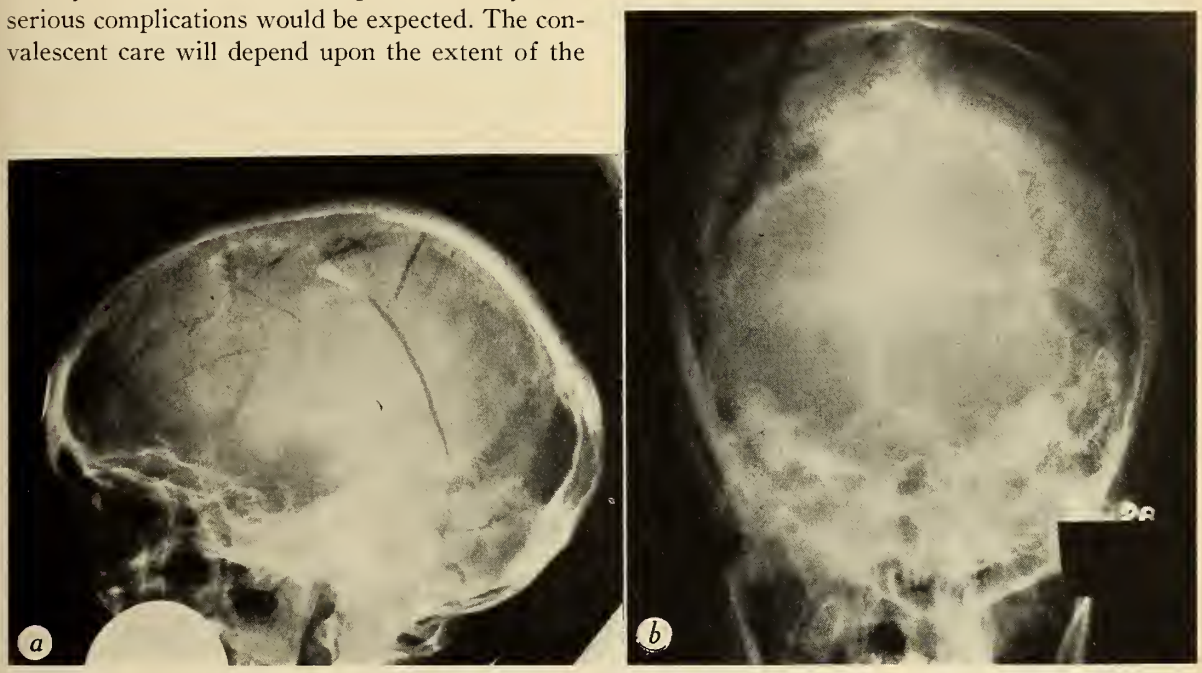

Fig. 4. Compound comminuted fracture of skull; *a*, lateral vew; *b*, posterior view.

Operative Treatment. — Lacerations of the scalp, compound fractures of the skull, depressed fractures of the skull, hemorrhages (extradural, subdural, and intracerebral and intraventricular), and the removal of foreign bodies, ordinarily necessitate an operative procedure.

Lacerations of the Scalp.—Lacerations of the scalp require a careful and painstaking débridement under local anesthesia or intravenous anesthesia with pentothal sodium. In Figure 3 are represented the nerve supply to the scalp and the manner in which an agent for the production of local anesthesia should be infiltrated into the scalp. The scalp should be shaved and cleaned with green soap and sterile water. Tincture of merthiolate and sulfanilamide powder can be used antiseptically in the wounds. The edges of the wound can be sutured with silk or silkworm catgut, and it is rarely necessary to institute drainage. Tetanus and gas gangrene antitoxin should be administered.

For some of the patients it is necessary to employ anesthesia, and in such cases, ether administered by the drop method over an intratracheal tube can be used when available. Local infiltration of the scalp with benzoyl-gamma-(2-methyl-piperidino)-propanol hydrochloride (metycaine) or procaine hydrochloride probably is the method of anesthesia most widely used in this type of emergency. The ideal treatment of this group of patients probably approximates rather closely the outline which follows.

Compound Comminuted Skull Fractures.—In the presence of such injuries the surgeon should:

1. Carry out débridement of scalp, fragments of skull and herniated brain
2. Elevate and remove bony fragments and foreign materials
3. Remove foreign bodies and metallic missiles when possible
4. Aspirate necrosed portions of brain from traumatic sinuses
5. Irrigate traumatic sinuses with a suspension of sulfanilamide in sterile water

6. Dust the surgical field with sulfanilamide
7. Close the dura when possible with interrupted sutures of fine chromic gut
8. Close the scalp with interrupted sutures
9. Use Penrose wick drains if injury is of more than six hours' duration
10. Administer tetanus and gas gangrene antitoxin
11. Administer sulfanilamide orally, being extremely careful not to overdose.

In the presence of comminuted fractures with depression of bone (Fig. 5*a*), it is necessary to elevate the fragments and then replace them, if possible. However, any fragmented portion of bone which is entirely separated from the periosteum should be considered as a foreign body and removed at the time of the initial operation. At times, in civilian practice, in the region of the orbit (Fig. 5*b*), the pieces of bone can be replaced when they are still attached to the periosteum and they may heal with very good results. During military engagements, however, this may not be advisable because of the risk of infection and subsequent formation of brain abscess and osteomyelitis. Basilar fractures should be treated according to the nonoperative dehydrating program unless severe hemorrhage occurs within the skull. It may be necessary to explore surgically through a temporal approach, to control the hemorrhage and then to follow the dehydrating program. Fractures of the skull which extend through the nasal sinuses or into the middle ear can be treated as compound comminuted fractures, in the case of the nasal sinuses, and as a basilar fracture in the case of the middle ear. A cerebrospinal fistula may result in either case and may require a surgical repair by an intracranial operation after the injuries to the brain have subsided.

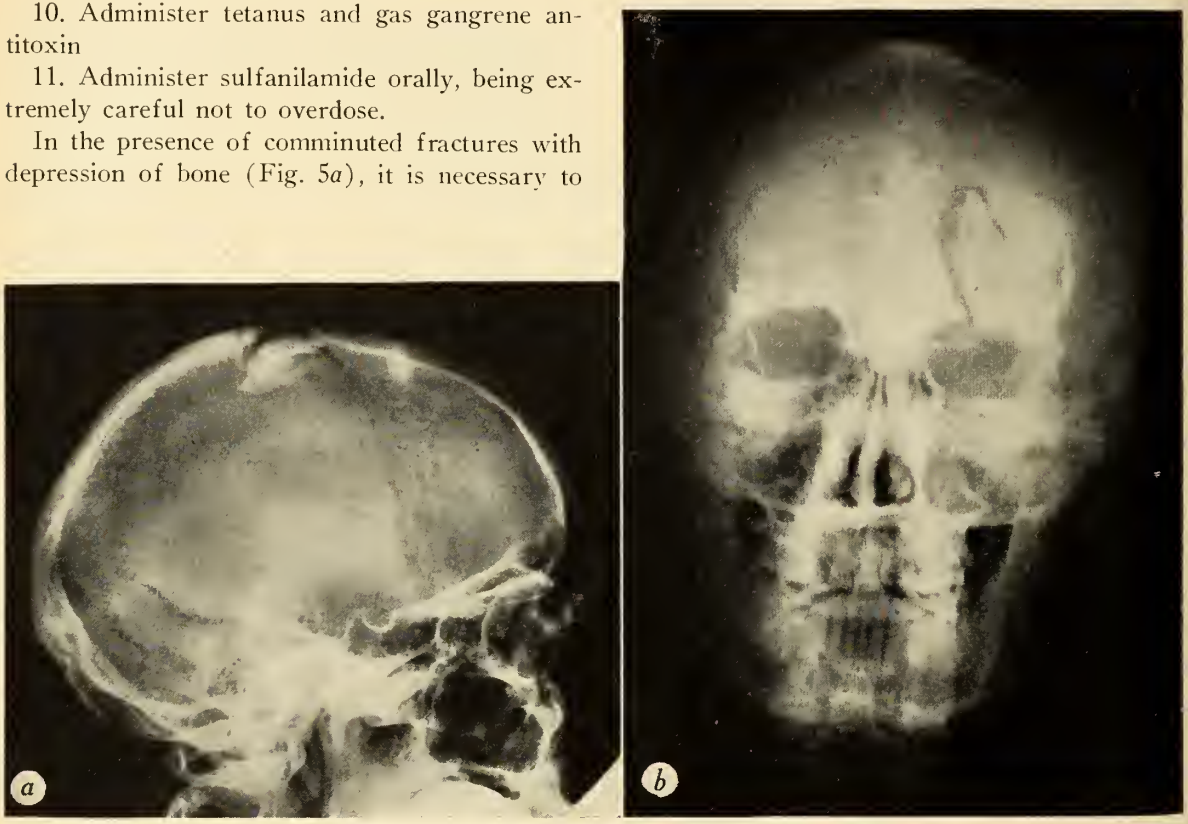

Fig. 5. *a*, Compound depressed fracture of the skull; *b*, fracture of the skull through left frontal sinus, with extension into the left orbit.

Hemorrhages.—There are four types of hemorrhage which may be encountered within the skull: (1) extradural, (2) subdural, (3) intracerebral and (4) intraventricular. Extradural hemorrhage usually results from a tear of the middle meningeal artery and usually is associated with a very rapid onset of symptoms, such as unconsciousness and hemiplegia on the contralateral side and, frequently, a dilated pupil on the homolateral side. In such a case it is necessary to trephine the skull through the temporal region and evacuate the clot. The injured portion of artery can

be treated by electric coagulation or ligated with silk or catgut sutures.

Subdural hematoma is very slow in onset and produces very gradual compression of the brain, as was demonstrated in Figure 2*a*. It may require weeks or months before the symptoms are recognized. Drainage of the old blood through multiple trephine openings in the skull usually is sufficient to relieve the patient, but at times craniotomy is necessary to permit evacuation of an organized clot.

Intracerebral hemorrhage can be treated by evacuation of the clot and institution of drainage through the traumatic defect in the skull, or by craniotomy.

Intraventricular hemorrhage is to be treated as acute internal hydrocephalus: by ventriculostomy and drainage.

Postoperative Care.—The postoperative care of patients who have received surgical treatment for craniocerebral injuries usually will approximate the outline which follows. The surgeon should:

1. Limit the intake of fluids to 1,800 c.c. for three days
2. Increase the intake of fluids gradually to normal values after three days
3. When sulfanilamide is used, control concentration so that it is between 8 and 10 mg. per 100 c.c. of blood
4. Continue the use of sulfanilamide for ten days unless there is evidence of craniocerebral infection
5. Afford ample drainage of infected wounds
6. Remember that brain abscesses are most effectively drained after encapsulation has taken place (duration of two to three weeks)
7. Institute dehydration, if it is necessary, to combat cerebral edema during the first three to six days, accompanied by (a) the intravenous administration of 1,800 to 2,000 c.c. of a 10 per cent solution of glucose per day; (b) the daily oral administration of magnesium sulfate, or 2 ounces of it (60 c.c.) in 3 fluid ounces (90 c.c.) of water given as an enema
8. Perform spinal drainage occasionally as indicated, when the patient is very restless
9. Avoid the occurrence of excessive dehydration
10. Administer 1½ grains (0.1 gm.) of phenobarbital twice daily to prevent convulsions
11. Institute feeding by tube if patient continues to remain unconscious after three days; this is to be accompanied by the giving of nourishment, proper amounts of vitamins and an occasional saline cathartic agent
12. Control pain and restlessness by use of the more potent barbiturates, such as nembutal, and when the patient has extreme pain, pentothal sodium.

Convalescent Treatment.—Convalescent treatment sometimes is a major problem in war casualties. Rest in bed is advisable until the patients' wounds are healed, unless the patients are mentally alert, in which case they may be permitted to be up five or six days after surgical treatment. They should be encouraged to return to active duty when their sense of well-being has returned. They should be given assurance that they are able to carry on their duties in a manner similar to that which existed prior to their injuries. For those unfortunate patients who have been maimed or in whom traumatic aberrations have developed, vocational guidance should be arranged so that they can be taught occupations, and can enjoy their existence in spite of their handicaps.

Sequelæ.—Many sequelæ may develop after a craniocerebral injury. Posttraumatic headache and vertigo are rather common. Among those patients who have received severe damage to the brain, monoplegia or hemiplegia may occur and remain permanently. Posttraumatic epilepsy occurs among a fair percentage of patients, and it is wise to wait two years before determining whether or not epilepsy will develop in a patient after damage to the brain. Meningitis may follow infection of the brain, and should be attacked specifically by chemotherapy when the causative organism can be isolated. Brain abscess should be drained after the infection has localized and the capsule has established itself. Cerebrospinal rhinorrhea may predispose to meningitis and brain abscess, and should be treated surgically by intracranial closure of the rent in the dura. Traumatic neuroses and psychoses are common occurrences among men in military engagements who have received minor injuries. They are also common among people who are not under the stress and the strain of a military engagement. Cerebral herniation may follow large

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL

A. J. Hertzog, M.D., and S. V. Loisness, M.D.
Pathologists

Presentation of a Case

Dr. Moosnick: This is the case of a nineteen-year old unmarried girl admitted to the contagion service of this hospital on December 28, 1942. She was complaining of malaise, weakness, headaches, vomiting, swelling of her ankles and bleeding from nose and mouth. Her medical history began at the age of six years when she suffered an attack of what she described as acute kidney disease. She had to remain in bed for several weeks. After this period in bed, she led a normal life and went to school. At puberty, although her breasts and other secondary sex characteristics developed normally, she never menstruated. Two years ago, in 1940, she noticed for the first time slight swelling about her eyes on awakening in the morning. In 1941, she noticed that she tired rather easily and suffered from vague muscle and bone aches. She could not specifically state what was wrong. In 1942, she was treated by a physician for the persistent amenorrhea with a series of estrogenic hormone injections. These were given as frequently as four or five times a week without producing any change in her menstrual status. In November, 1942, she applied for work at one of the defense plants and was rejected because of severe albuminuria and a systolic blood pressure of 180 mm. She applied at another plant and was accepted after a physician examined her urine grossly. She stated that he had only looked at the specimen. She worked for about two weeks but had to resign due to increasing weakness and moderate shortness of breath on exertion. At this time she noticed for the first time urinary frequency and nocturia, and persistent nausea and vomiting. She began to bleed from the nose and mouth and developed a pustular eruption over the face. She remained in bed at home for a few days and then was admitted to a private hospital. Her physicians found evidence of uremia and of marked anemia—her hemoglobin was only 26 per cent. She was given twelve small blood transfusions which raised her hemoglobin, but the bleeding tendency persisted. Her throat became congested and ulcerated and culture showed diphtheria bacilli, so she was transferred to the contagion service of this hospital. Her family history was pertinent in so far as her mother had suffered from severe hypertension and had died at the age of forty-eight years, shortly after the birth of a child.

Physical examination on admission revealed a well developed, stocky girl of nineteen years. There was a uriniferous odor to her breath. She was lethargic, responded poorly to questioning, and appeared very ill. The skin showed numerous diffuse petechial hemorrhages and a few pustules, mainly on the face. The breasts were well developed. The mucous membranes of the mouth and throat showed numerous small ulcerations and bled rather easily. Her temperature was 100.4. Blood pressure was 130/115. The pulse rate was 100 per minute. A soft systolic murmur was present at the apex of the heart. The lungs were clear. Abdominal examination revealed nothing of note. A pelvic examination was not done. The eyegrounds showed marked bilateral hemorrhages and exudates.

A throat culture showed diphtheroid organisms resembling Corynebacterium diphtheriæ. However, these proved to be nonvirulent after guinea pig inoculation, so she was transferred to the medical service. Four urinalyses showed a specific gravity that varied from 1.010 to 1.017; albumin from 3 to 4 plus; red blood cells varied from 3 to 15 per high power microscopic field. A few leukocytes were also present but casts were not seen. Blood urea nitrogen varied from 188 to 194.6 mg., creatinine from 9.4 to 11.5 mg., and uric acid was 15.4 mg. Hemoglobin determinations ranged from 77 to 66 per cent (Sahli). Red blood counts varied from 3,860,000 to 3,260,000, and white blood cells from 6,600 to 9,900. A platelet count was 94,000. Differential counts showed 82 to 95 per cent neutrophiles. The leukocytes were toxic and the red blood cells showed slight anisocytosis, hypochromasia and polychromahtophilia. A sternal bone marrow aspiration was done. The marrow was reported as showing toxic regeneration of the erythroid and myeloid elements. There was a marked diminution of megakaryocytes with little tendency to platelet production. A sedimentation rate was 89 mm. for one hour. Bleeding time was 15 minutes, and coagulation time was more than 9 minutes. The prothrombin level was 62 per cent. Total plasma proteins were 6.9 grams. The carbon dioxide combining power of the plasma was 60 volumes per cent.

She was given a blood transfusion and treated symptomatically, but her condition rapidly became worse. Her mild fever persisted and she bled intermittently from the nose and mouth. She vomited frequently, and developed a cough productive of a small amount of bloody sputum. Her urinary output was 200 to 600 cc. daily. She remained stuporous, muscular twitching appeared in her face, her breathing became irregular and she died on January 1, 1943.

Dr. Hertzog: The history of kidney disease in this case goes back for thirteen years. The story is that

of chronic glomerulonephritis with a slowly progressing renal insufficiency. This case shows the necessity to perform guinea pig inoculations as a virulence test before finally accepting any diphtheroid organism as pathogenic, especially in the clinical absence of diphtheria. Did anyone have an explanation for the amenorrhea?

DR. MOOSNICK: We had none. We did not do a pelvic examination because her condition was critical. The history was of no help. We only knew that she had received parenteral therapy for the amenorrhea over a period of months with no benefits.

INTERN: What type of skin lesions did she have?

DR. MOOSNICK: She had two types of skin lesions. One was diffuse petechial hemorrhage and the other was small pustules.

PHYSICIAN: Did she have any evidence of heart failure?

DR. MOOSNICK: She had no physical evidence of heart failure. Her venous pressure was 10 cm.

DR. HERTZOG: The laboratory findings in this case are obviously those of uremia. It is of interest that no casts were found in her urine. We can attribute the anemia largely to chronic nitrogen retention. Anemias in cases of azotemia are usually of the normocytic variety and respond poorly to therapy. Significant lowering of the blood values is not common unless the blood urea nitrogen remains for some time above 50 mg. per cent. This has apparently a direct inhibitory effect on the bone marrow. The specific factors in connection with the azotemia that are responsible for this effect are not known. Purpuras are not uncommon with uremia. In this case both the peripheral blood and the bone marrow showed a thrombocytopenia. The bleeding and coagulation times were prolonged. A cuff test for capillary resistence would probably have shown increased capillary permeability.

STUDENT: Did she have an upper respiratory infection before admission?

DR. MOOSNICK: It was difficult to tell because she had dried blood and dried secretions in her nose and throat.

DR. HERTZOG: If there are no further questions or discussion, Dr. Lofsness will give the autopsy findings.

DR. LOFSNESS: The body was rather short, being only 4 feet, 10 inches in length, but it was well developed and well nourished. There was slight edema of the face and ankles. There was a skin eruption as Dr. Moosnick described. There was a small absess at the tip of the left ring finger. The right pupil was smaller than the left and a hemorrhagic conjunctivitis was present on the right. The abdominal cavity contained approximately 500 cc. of clear fluid. The liver weighed 1300 grams and showed no gross evidence of passive congestion. The spleen weighed 100 grams and appeared normal. The heart weighed 325 grams and showed slight hypertrophy of the left ventricle. The right lung weighed 625 grams and the left 340 grams. Both showed patchy areas of hemorrhagic broncho-pneumonia, especially the right lower lobe. Both adrenal glands were situated in their normal position but underlying kidneys were not found. A search of the pelvis revealed a single mass attached to the bladder. This proved to be a solitary kidney. The ureter was only 10 cm. long and showed slight dilatation; it entered the bladder on the posterior wall 2 cm. above the urethra. The single kidney weighed 125 grams. The cortex was thin, yellow and pitted as seen in chronic glomerulonephritis. External examination of the genitalia showed normal labia and a normal urethral orifice. There was a dense, imperforate hymen. Further examination of the pelvis revealed a complete absence of Fallopian tubes, uterus and vagina. The ovaries were present. Both were embedded in the lateral pelvic peritoneum. They were of normal size and showed evidence of recent ovulation. The only other significant findings were enlarged parathyroid glands. Four glands were found and these weighed 50 mg., 85 mg., 150 mg., and 150 mg. respectively.

PHYSICIAN: How much larger than normal are these figures for the parathyroids?

DR. LOFSNESS: The upper glands were approximately twice the normal size, while the lower glands were approximately four times normal. Mallory gives 30 to 45 mg. as the average weight of a parathyroid gland. I will now show the microscopic sections from this case. The kidneys show the usual picture of chronic glomerulonephritis. There are many hyalinized glomeruli. The remaining glomeruli are overly cellular and there are a few epithelial crescents. There is extensive tubular atrophy. The remaining tubules are dilated and contain casts. The blood vessels are not remarkable. The next slide is from the lower lobe of the right lung. It shows extensive hemorrhagic bronchopneumonia with the alveoli filled with red blood cells and neutrophiles. The last slide is that of the ovaries. Normal ova and follicles are present. I do not have the slides of the parathyroids to show you as they are at the University; however, they show simple hyperplasia. Hyperplasia of the parathyroids is common in chronic renal insufficiency regardless of its cause. The renal insufficiency leads to a retention of the phosphates, which are ordinarily excreted in the urine, and this depresses the calcium level of the blood. Calcium is excreted by the bowel and this is little influenced by the uremia. Apparently the parathyroids hypertrophy and mobilize calcium from the bones in an effort to maintain the blood calcium at a normal level, but the calcium is excreted as rapidly as made available. If continued long enough, this leads to some osteoporosis. In chidlren, this interferes with growth and may lead to dwarfism. Our patient had no blood calcium determination, but had clinical signs of hypocalcemia, such as muscular twitching.

DR. HERTZOG: Dr. Bell reports a single kidney as occurring in one out of nine hundred persons. Usually the corresponding ureter is entirely absent, but in a small percentage of cases remnants of the ureteral bud may be seen. The single kidney is usually larger than one of normal size. The kidney in this case was smaller than normal because of the chronic glomerulonephritis. Renal agenesis is due to defective development of the mesonephros and the Wolffian duct. The ureteral bud normally arises from the terminal portion of the Wolffian duct and grows to join the metanephric blastema, where it gives rise to the pelvis and the collecting tubules. Due to agenesis of the terminal part of the Wolffian duct, the ureteral bud fails to develop. The metanephric blastema does not differentiate into tubules if contact is not made with the ureteral bud. Congenital anomalies of the genital organs are found in a large percentage of cases of unilateral kidney. Bell estimates that two-thirds of the females with unilateral kidney show malformations of the uterus and tubes due to the close embryological relationship between the kidney and genital organs. In males with unilateral kidney, there is often unilateral absence of the ductus deferens, ejaculatory duct, seminal vesicle and sometimes a part of the epididymis.

Anatomical Diagnosis: (1) Chronic glomerulonephritis; (2) solitary kidney; (3) uremia; (4) congenital absence of uterus, Fallopian tubes and vagina; (5) bronchopneumonia.

HISTORY OF MEDICINE IN DODGE COUNTY

BY JAMES ECKMAN

Rochester, Minnesota

and

CHARLES E. BIGELOW, M.D.

Dodge Center, Minnesota

(Continued from February issue.)

The oft-repeated contention of Professor Frederick J. Turner,[9] that "the existence of an area of free land, its continuous recession, and the advance of American settlement westward explain American development," seems amply confirmed in the case of Dodge County and its physicians. Attracted to the new and rich lands which could be theirs by the simple but by no means easy task of breaking and holding them, they slowly infiltrated the region in the middle fifties, and streamed into it in the sixties in profusion. Once settled, they discovered that the physiologic processes of life and death had been in no wise deterred, however salubrious the new country might have seemed to them. One Morris Dolson was born on May 15, 1854, in what is now Concord, only three days after his mother and father had arrived from Dubuque, and not even a day after a cabin had been erected frantically for the pastoral *accouchement*.[5] It was the first birth in the county. During the fall of 1854 and the winter of 1855, in what is now Milton Township, the people were afflicted with smallpox, "which the Indians transmitted to a portion of the settlers."[5] In February of 1855 one Mrs. Mastin died in what is now Kasson, "the first death of a white person in the town or county."[5]

A native of Vermont, **Dr. Josiah R. Dartt** (1824-1874), was the first physician known to have come to Dodge County to remain, and he may have ministered to the settlers stricken with smallpox, for he came to Dodge County in the fall of 1854, according to some.* When Governor Willis A. Gorman (1816-1876) appointed the officers of Dodge County on August 4, 1855, he selected Doctor Dartt as treasurer, an office which the physician occupied only until the ensuing October elections, in which his successor was chosen.[5]

Doctor Dartt may have had some broken heads to mend from time to time, for Nute[10] has shown that in 1855 there existed what was called the "Dodge Centre Claim Society,"** composed of frontiersmen who never shrank from exerting "a little gentle force"[10] when they came upon settlers whom they considered undesirable. Doctor Dartt himself was the executive of a committee of vigilantes formed at Mantorville in 1855.[11]

The venerable **Dr. Samuel B. Sheardown** (1826-1889), first president of the Winona County Medical Society[12] (1869) and treasurer of the Minnesota State Medical Society from its reorganization in 1869 until his death in 1889, seems to have had a part in bringing the next physician to Dodge County. Doctor Shear-

*The authors, as a matter of fact, do not know when Dr. Dartt came to Dodge County, although he did so in either 1854 or 1855. In the biographic section of this essay will be found a more extended discussion of this point, in the sketch of the life of Dr. Dartt.

**But it is to be noted that the *village* of Dodge Center was not founded until 1866.

down was one member of an early company of Winona land speculators, composed of such well-known men as General William Windom (1827-1891), United States Senator Daniel S. Norton (1829-1870) and others, who in the summer of 1855 platted the village of Ashland† in Dodge County as a speculative undertaking in real estate. Associated with them in this venture was **Dr. George W. Townsend** (1832-1910), who built and stocked a store in the new village. He sold this store in the spring of 1856. Eventually, he moved to Steele County.*

At some time in 1855 Doctor Dartt and Doctor Townsend were joined by **Dr. James Mansfield Ryder** (1822-1900), a homeopathic physician. He came from Dryden, Michigan, and like all the pioneer practitioners, took a farm as a homestead. His land was situated in Milton Township, and he lived on it and practiced medicine among his neighbors for about thirty-five years, except for the period of his services in the War of the Rebellion.

Close on the heels of Doctor Ryder came **Dr. Staunton B. Kendall** (1808-1897), who in 1856 pre-empted farm land near Ashland and practiced homeopathic medicine among his neighbors. On May 11, 1858, he was elected first assessor of Ashland. He left Ashland Township in 1862, after "the people became suddenly aware that it was an excellent farming section but that a village of much pretensions would hardly be built."[5]

In the spring of 1856 **Dr. William P. Miller** (1806-1873), a homeopathic physician from Ohio, and **Dr. James A. Garver** (1814-1901), a "regular" physician from Ohio and Indiana, came to Wasioja together. Doctor Miller opened a combination dry goods and drug store and undertook the practice of medicine.[5] No doubt one of Doctor Miller's patients was his own brother, Augustus Miller, who died in the summer of 1856, "the first adult to leave this place [Wasioja] for that undiscovered country, from which none ever return . . ."[5] It was recorded that "Doctors Garver and Miller entered upon the duties of their profession whenever sick people could be found, but the country was so free from disease that they found but little to do."[5]

Dr. James A. Garver likewise settled at Wasioja, where he homesteaded a farm just north of the village. He was a graduate of the Medical College of Ohio and a brother-in-law of Doctor Miller. He remained at Wasioja until 1875, in which year he moved to Dodge Center, where he lived and practiced medicine for the rest of his life.

It might be said, parenthetically, that Doctor Miller and Doctor Garver came to what is still one of the most beautiful sections of Dodge County or even Southern Minnesota. Situated on one of the branches of the Zumbro River, and surrounded by immense white pines which cover the Zumbro bluffs, far west of the general geographic range of these trees, the hamlet of Wasioja more than rewards the traveler with its graces.

Like many another frontier physician, Doctor Garver at first was forced into pursuits other than his chosen profession in his efforts to sustain himself, and he became the manager of a hotel, the Wasioja House, built by the proprietors of the town of Wasioja. How successfully Doctor Garver at least once added to his meager professional fees may be judged from the following paragraph:

> . . . having to leave home one day, he left the house in charge of C. H. Moses, with strict injunctions against receiving more guests than could be comfortably accommodated. Upon returning somewhat late at night, he found his guests stowed away at the rate of three in a bed in each of the rooms, and the "school section" "farmed out" in an equally

†These men gave the name "Ashland" to what is now Ashland Township in Dodge County. See reference No. 17.

*A Dr. George Townsend, however, was practicing medicine in Winona in 1865. The authors do not know that it was the same Dr. Townsend mentioned above.

productive manner, while the sitting room floor was occupied by as many as could find lodging on the carpet. This, though not quite what he would have liked for his guests, was a very good thing for the doctor, and swelled his funds in the sum of $120.[5]

In 1858 he became the first clerk of the Congregational Church of Wasioja, which in 1875 was moved to Dodge Center.

Another arrival in the county in 1856 was **Dr. T. G. Ingraham.** He settled at Concord, where he pre-empted land and served as one of the recorders for the village which was originally platted in the spring of 1856.[5] He erected a general store in association with Benjamin S. Cook (1833-1905) in Concord, and was also chairman of the first board of supervisors and justice of the peace in Concord Township in 1858. It is not known whether he held the degree of Doctor of Medicine. He was a county commissioner in 1859[5] and a county appraiser of school lands in 1864, and it is known that he was in Dodge County until 1865, for early in that year he resigned his post of register of deeds. Mr. Charles Woods,[13] who was born in 1857 on a farm southeast of Concord, reported that he could remember Doctor Ingraham. He said that Doctor Ingraham was the physician who attended his mother when he (Woods) was born.

It was in 1856, also, that typhoid fever killed several members of a German family living in the county,[14] but the disease apparently did not spread further. Venomous snakes seem to have been prevalent in the county in the early days, as Lord[1] has said, and snake-bite probably was a common accident. It was written:[14] "The writer knows two or three persons who also had experience with the effects of snake-bite poison, and who escaped, though not without terrible suffering." It was said that rattlesnakes were discovered in such odd places as a wash boiler, a sleeping man's pocket and in a bedtick filled with hay.[14] On almost any night the settlers could hear the hoarse howling of the prairie wolves, which so far as is known inflicted no wounds on human beings.

It is believed that a **Doctor Sarven** was in Dodge County in 1857, but very little is known about him. He seems to have settled in or near Concord. When the first Dodge County fair was held in Mantorville in 1857, it was said[15] that members of the committee for the fair were Doctor Ingraham, Doctor Townsend, Doctor Rice and Doctor Sarven.

Dr. Edward Payson Kermott (1825-1872), a Canadian eclectic physician, is known to have been in the new village of Rice Lake in 1857. At least part of the time he extracted teeth for the settlers, and there is no reason to believe that he employed an anesthetic agent for such procedures. Doctor Kermott soon moved to Wasioja, it would appear, where in 1860 a son, Edward Plews Kermott (1860-1938), was born to him. This son also became a physician, although he did not practice medicine in Minnesota. The career of Dr. Edward Payson Kermott will be considered later herein.

Several more physicians came to Dodge County during the latter part of the fifties, in spite of the evils to which the settlers were exposed. The *Mantorville Express* during 1857 and 1858 contained the professional card of **W. A. Fessenden, M.D.,** in which it was stated that his office was at his residence and that he lived at Sacramento, Dodge County. Nothing more is known about him.

Sacramento itself is interesting as a "ghost town." It was platted in about 1857 between Wasioja and Mantorville on the Zumbro River, by a calculating fellow who apparently contrived to turn news of the "gold strike" at Oronoco in 1856 to his own advantage. He was said to have buried gold nuggets along the Zumbro River near his townsite to attract those whose imaginations had been inflamed by reports of deposits of gold

along the same stream near Oronoco in Olmsted County.*[16] He shrewdly chose the name "Sacramento" because of its connotation of the California gold fields, it has been said.[17] Sacramento eventually thrived to the point of being able to challenge Mantorville for the county seat in 1857, but was defeated by popular vote. Today all that remains of Sacramento is some old stonework of the mill that was built there when the village was established. The Sacramento House, opened with some pride in May of 1858,[18] was later moved to Kasson, where before it burned it was known as the American House.

On March 25, 1858, the *Mantorville Express* announced that **Dr. Augustus O. Potter** had lectured on "The Use of Alcohol," and it can be assumed that he had been in the county for a time previous to his talk. He came to Mantorville from Pennsylvania, and remained there until the outbreak of the War of the Rebellion, in which he lost his life. Lord[1] called him a "pioneer doctor of more than local renown," with an "unusual talent for surgery."

It was in this year (1858) that Doctor Dartt explored Western Minnesota and the Territory of Dakota. He sent back letters about his trip, in which he said that the soil of the regions he had visited was no better than that of Dodge County.

The physicians who had come to Dodge County were scarcely well settled before the great panic of 1857 swept the land. What effect this panic had on Dodge County is not readily apparent, for it is not described in earlier sources, possibly because it was believed that any reference to it would discourage much-needed emigration. The panic certainly retarded the development of many a town and obliterated others entirely. As Blegen[19] wrote: ". . . every town in Minnesota considered itself a potential metropolis, and town-site speculation reached a frenzy before the panic of 1857 descended like a blight upon the territory." Ashland was one town in Dodge County which was extinguished by the panic of 1857 and other factors.

It is certain that those who lived by the soil, which at this time included the physicians of Dodge County, were sorely oppressed. Bassett[20] wrote: "The West suffered most; for at this time the Crimean war was ended, and a large area was thrown open to wheat cultivation, on account of which the price of that commodity fell from $2 to 75 cents a bushel, entailing ruin to producers and all who depended on them."

One of the effects of the panic of 1857, which surely influenced the influx of physicians to Dodge County, was what seemed to be a catastrophic delay in the construction of railroads within the state. Larsen[21] detailed the situation:

> The panic of 1857, however, struck Minnesota with such force that the railroad companies were paralyzed. It was at this time that the people of Minnesota ventured into the field of public railroad financing. The framers of the state constitution, harking back to the lessons learned from the panic of 1837, specifically forbade the use of state credit for financing private enterprises. The state's credit, however, was precisely what was wanted, and so in the spring of 1858, an amendment to the constitution was voted whereby the credit of the state could be used to the extent of five millions of dollars to aid the construction of railroads. Accordingly, the Minnesota state railroad bonds, for which the lands of the companies were held as security, were issued. For a few months railroad financiers enjoyed a period of frenzied activity. The money secured by the loan of the state credit was dissipated, however, and though some grading was done, not a foot of railroad was built.

*It is interesting to observe that in 1857 an early Minnesota physician, Dr. Charles W. Le Boutillier of Minneapolis, perpetrated a similar hoax by "planting" gold nuggets and gold dust at the head of Nicollet Island at Minneapolis. See: O'Brien, F. G.: Minnesota Pioneer Sketches, Minneapolis, H. H. S. Rowell, Publisher, 1904, pp. 241-242.

Not until the sixties did the railroad penetrate to Dodge County, and when it did it caused some towns to disappear entirely and new ones to arise. Much money pledged by the settlers toward certain railroad ventures or developments was lost irretrievably, and in some cases railroad lines which had promised to include certain towns passed them by completely when roadbeds were built. The history of the iron horse in Dodge County is not felicitous.

To add to such vicissitudes, a terrific hailstorm visited the county in 1858, beating down the grain wantonly and destroying much of the settlers' labors in the establishing of permanent lodgings and settlements. Funds and assistance were obtained from outside the county, and Doctor Garver was one member of a committee that was organized to distribute relief to the stricken pioneers. Some of the disheartened left the county; but by far most of the settlers remained. Doubtless their spirits were cast down and their hearts unsure as to the future. As it happened, however, these were the worst years of the county, and were soon left behind. The years 1859 and 1860 seem to have been favorable ones, in relation to agricultural pursuits.

It is worthy of note that by the summer of 1857 Dodge County had two newspapers: the *Wasioja Gazette* and the *Mantorville Express*, both initiated in the summer of that year.[5]* These were among the first newspapers in the rural areas of the Territory of Minnesota, and it was the privilege of one of them[22] to announce to the settlers of Dodge County the fact that Minnesota had been admitted into the Federal Union:

> Our growth has been so rapid that our Territorial habiliments were entirely unfitted to our needs. The machinery of a Territorial Government was inadequate to meet the wants and demands of the population. The destiny of Minnesota is now in the hands of her own people. May it ever be onward and upward! May she ever be found among the foremost in moral and political reform, as well as in physical wealth and happiness!

In 1857 and 1858 a homeopathic practitioner named **W. H. Rice** seems to have practiced medicine to some extent from his farm about a mile and a half east of Mantorville. The *Mantorville Express* contained several of his professional cards or notices during the aforementioned period, and it is thought that Doctor Rice remained in the county until after the War of the Rebellion. He exemplifies again the pioneer physician who could not subsist on the frontier by the proceeds of his practice alone, and had to resort to the land for a living. Nothing more is known about Doctor Rice.

Nute,[10] speaking for the Minnesota Historical Society in 1926, said that "A very attractive volume of letters and reminiscences of the oldest settlers of Mantorville was received last year by the society," but the authors have not seen this volume, unless it should happen to be the *Recollections of Mantorville*, by Samuel Lord,[1] which they have examined. At any rate, it would be most desirable to learn more about Dr. W. H. Rice, as well as other pioneer physicians who practiced in or near Mantorville.

---

*Files of the *Mantorville Express* owned by the Minnesota Historical Society are remarkably complete. The society also owns a few copies of the excessively rare *Wasioja Gazette* for 1857, 1858 and 1859. See: Minnesota History, 11:95 (March) 1930.

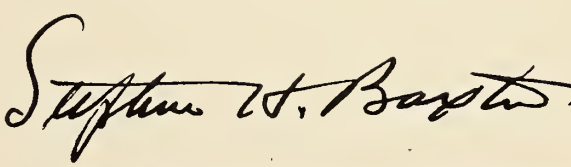
President's Letter

TEMPORARY EXPEDIENTS



ON February 14, the seventeenth annual meeting of the National Conference on Medical Service was held in Chicago. The importance of this annual conference is probably enhanced by the very fact that it is unofficial, has no membership list, collects no dues, is purely a voluntary body that exists as an organization largely because it has a president and a secretary. It is not in any sense a "pressure group," but may be considered as a fair cross-section of the professions of Medicine, Dentistry and Hospital Administration. All members of these professions are invited to attend the conference and to participate in the discussions. It has no program to champion, no pet schemes or theories to promulgate, but it meets to consider in free and informal discussion, the broad aspects of things which affect the quality of medical service.

Under the general caption, "Analysis of Current Trends in the Control of Medicine," the conditions which confront Medicine, Dentistry, and Hospitals were discussed by leaders in their respective fields. The subjects were different, the personalities of the speakers were different, but a keynote seemed to run, with varying degrees of emphasis and distinctness, through all the addresses. This keynote was struck most clearly by Senator Burton, of Ohio, in his address at the noon dinner of the Conference. He compared the guiding of the course of the nation through a crisis such as exists today, with the plotting of a course for a ship setting out on a long voyage. The navigator must solve both the immediate and the long-distance problems. He will determine the direction that he must follow to reach the distant port and will follow that course by compass and observations of the stars. The immediate problem before him, however, is entirely different. Before he reaches the open sea where he can steer his ship by the stars, he must avoid the rocks and shoals near shore and thread a crooked channel with many changes of direction, steering not by fixed stars but by local landmarks and frequent soundings. These changes in direction are necessary to avoid dangers close at hand, but the experienced navigator will never be deceived by such changes in direction. He will again steer his ship by the stars when he reaches the open sea.

Seductive arguments are put forth favoring the lowering of educational standards in order to hasten the graduation of a larger number of medical students. Sympathies of legislators and governmental officials are played upon, to induce them to relax the restrictions on the practice of medicine, and to permit practitioners whose qualifications are questionable or unknown to practice under a "temporary license."

A wise man once said that there is nothing more permanent than a temporary expedient. Men are prone to follow the line of least resistance and to permit the temporary expedient to become permanent policy rather than to fight to abolish it. Reducing the quality of service, lowering standards of education and relaxing the laws governing qualifications and licensure of practitioners would be simply playing into the hands of Charlatans and incompetents and worse, and cannot be justified on grounds of temporary necessity or expediency.

Temporary expedients may sometimes be necessary to meet present emergencies, but let us not forget that such expedients should be temporary; let us not be beguiled into believing that a temporary change in direction should take the place of our permanent, long-range course. This applies not only to the professions. Every citizen of this Republic should recognize this principle, for the problems of the professions are essentially the problems of America. We all belong to one Commonwealth which has prospered and grown strong under the "American way of life." It is a prime duty of those of us at home to see to it that temporary expedients are abandoned when the emergency is past and that the soldiers come back to the kind of America for which they are fighting.

THE DIAGNOSIS OF MULTIPLE MYELOMATA

THE age decades in which myelomata occur are the same in which benign progressive degenerates manifest themselves. The similarity of symptoms are periodic pains in the back, pains in the pelvic or shoulder girdles, the different anemias, and albuminurias. The marked disproportion of degenerative cases, as compared with the number of myelomata, and their mimicry, no doubt lulls to sleep the awareness of this condition in our daily routine.

Geschickter and Copeland's[1] classical paper marks the era which might be designated as the anatomical-pathological study period of the disease. It covers an interim of nearly eighty years (1845-1928) and includes 425 cases. Their criteria for diagnosis are: (1) "multiple involvement of skeletal trunk of adults"; (2) "pathological fracture of a rib"; (3) "the excretion of Bence Jones bodies"; (4) "characteristic backache with signs of early paraplegia"; (5) "an otherwise inexplicable anemia"; (6) "chronic nephritis with nitrogen retention and low blood pressure."

These "taken in pairs or triads or collectively as a group" should make one aware of myelomata. There is a residue of cases, however, in which some finding or factors appear which are misleading. A recent case with a spontaneous fracture of the fourth lumbar vertebra with paraplegia, and a fractured rib (x-ray) certainly suggested myelomata. There was, however, an anomalous kidney finding (pyelogram) and the opinion turned to hypernephroma with bone metastases. At postmortem a diagnosis of myelomata was made. Again, a case was observed for twenty-four years. Painful hands, secondary anemias, albuminurias, gastro-intestinal symptoms, et cetera, recurred again and again. This patient had a complete skeletal review by x-ray three months before death. Atherosclerosis, lead poisoning, peri-arteritis nodosum, were considered and rejected. At postmortem, myelomatous infiltrations of the ribs were demonstrated. One wonders if the disease lasted twenty-four years or merely was a terminal event in the life of a septuagenarian. In both these cases, no test was made for Bence Jones bodies. Geschickter estimates these bodies are found in 65 per cent of myelomata. The impression is growing that their presence is more prevalent than that figure. It may be said that some time during the disease these bodies are present if persistently and correctly looked for. In the original test, nitric acid is used and not acetic acid to acidulate the urine. Not long ago, in trying to establish the presence of myelomata, the correct diagnosis was made by sternal puncture. Rechecking the urine for Bence Jones bodies, with nitric acid, they were found; whereas before, with acetic acid, the test proved negative.

Following the anatomical-pathological period, students of this disease made chemical studies of the blood to establish a differential method of diagnosing myelomata from invasive tumors of the bones and blood dyscrasias. Bence Jones bodies are occasionally found in these conditions also. Calcium, phosphorous, phosphatase, protein levels were established. Even iso-agglutinins and rouleaux formations were noted. These studies revealed variations of these findings in different lesions. In myelomata however, phosphatase, is not, or is only slightly, increased. This stage of the study of myelomata may be considered as the chemical period.

Now, a third period is under way. It is the use of the sternal puncture. The myelogram[2] may become almost as common as the hemogram. It is too early to say what this technique in the study of bone tumors will establish. However, the meager reports are most encouraging. The sternum is an early site for myelomatous nodes. Even if one is not lucky enough to puncture a node, the variation in the myelogram (increase of plasma cells) may put us on our guard.

With the prevalence of x-ray examinations and blood chemical studies, it is still pertinent to call attention to the simple test for Bence

Jones bodies in establishing the presence of bone destruction. Geschickter's criteria are invaluable. Chemical studies of the blood are worth while. Sternal puncture is promising. The test for Bence Jones bodies in the urine, which requires a minimum of apparatus, is still the most directive means we have in the diagnosis of multiple myelomata. H.L.U.

THE RED CROSS

IT was at the battle of Solferino in 1859 in the war between Napoleon III and Austria waged to liberate Italy and to annex Savoy and Nice to France that a Swiss by the name of Henri Dunant was a spectator. Being present and observing one of the bloodiest battles in history, Dunant was impressed with the need of a neutral organization whose function should be to mitigate as much as possible the suffering and unnecessary loss of life incident to war. He wrote "A Memory of Solferino" in which he described his experiences and as a result of his pioneering activities the first International Red Cross Congress was held in Geneva in 1863.

The American, Clara Barton, was in Berne, Switzerland, in 1870 at the outbreak of the Franco-Prussian War and joined the German Red Cross. On her return to the United States she devoted her energies toward persuading her countrymen to take part in this international humanitarian organization. After nine years of devoted effort our country ratified the Geneva Convention and we became the thirty-second nation to join.

The Red Cross has made a remarkable record in growth and usefulness since its foundation. While organized primarily for activity during war, its peacetime function at times of disaster is well known.

Nursing service in military hospitals has been one of the outstanding activities of the Red Cross and the Red Cross Nurse has been lauded in song and verse. One of the newer activities of the organization is the supervision of the Blood Donor Service, one of the more important innovations in the care of the wounded. In addition, the Red Cross has organized the nurses' assistants, the Gray Ladies, supervises the hospital recreation programs and service men's clubs overseas and maintains representatives at Army and Navy posts. In its home service work it assists the dependents of our fighting men. It must be prepared, too, to come to the rescue with trained personnel in case of disaster on the home front.

March has been declared Red Cross Month by our president. The usual roll call held in November was postponed from last November to March. This month a nationwide drive to raise a War Fund is being conducted in conjunction with the annual roll call. Only one appeal for funds this year is anticipated. A generous response is expected.

CAPITALISM DESIRABLE

SOMEHOW we have little fear of communism taking hold in our country. No communistic form of government has ever been successful. When put to the test in Russia, it resulted in the control of the government by a few who held their power through a system of force and terrorism just as undesirable as the Czarist régime. The fine showing of Russian defense must be attributed to the love of the Russian for his homeland rather than to the type of government.

Neither is a purely socialistic form of government with the elimination of capitalism ever likely to meet the approval of American citizens. The socialistic party in Germany met the same fate as communism in Russia, with the usurpation of power by a few brigands led by a psychopath which promises to result in the destruction of the country as well as the rest of Europe.

The elimination of capitalism will never meet with the approval of employer or labor unions. It is safe to say that as long as the majority of citizens in any country have private possessions to lose, there is no danger of revolution either violent or peaceful. Following 1929 the terms "capitalist" and "capitalism" were frequently referred to in a disparaging manner. Capitalism was blamed for the crash of 1929 and was considered by some a failure. Only shallow thinking fails to realize that any business enterprise requires savings or capital for its initiation. Anyone with a few hundred dollars saved is, strictly speaking, a capitalist. It takes savings and capital to make jobs and it is high time the approbrium be removed from the word "capitalist." It is the capitalistic form of social order which has

been the driving force that has made living in America better than in any other country.

The ambitious American who wants to accomplish things in a big way will want to continue our capitalistic form of society. Thinking leaders of unions know there would be no arguing with a socialistic government and, therefore, it is safe to assume that the majority of laboring men will never favor an entirely socialistic form of government.

Is there any reason to believe, if socialism in general will not be acceptable to the American citizen, that socialized American medicine will?

Socialized medicine abroad has been studied and most of the forms in use would not be acceptable to the American citizen. We are experiencing right now in this country a proof that the American citizen when he is able prefers to choose his own physician and hospital and pay for the service.

The all-inclusive British plan introduced in England by Sir William Beveridge will doubtless have its repercussions in this country. It is more than likely that a determined effort will be made to foist some such plan on our citizens on the grounds of war necessity.

Medical care in our country already has been socialized to a considerable extent. There are already as many hospital beds supported by government agencies as private. As a result of the war there is evidence of a tendency to increase rather than diminish the socialization of medicine. With the excuse of war emergency there is no telling what utopian plans may be suggested before the war is over. And after the war, what will be our economic status? It will require capital to provide new jobs for returning soldiers and high taxes will have to persist to pay interest on the already huge national debt. If the government is forced to supply the needed capital to furnish these new jobs, the transition from capitalism to socialism may be a simple matter. It will require a financial wizard in Washington to bridge the gap from war to peace economy.

For the medical profession to complacently sit back and oppose all change would be a mistake. To fail to resist complete socialization of medicine would be a betrayal of the American people. The profession should be and will be open minded in furthering plans proposed for the improvement of medical care at costs within reach of the public. The profession, as well as the public, are vitally interested in the preservation of capitalism, sometimes called the American way of life. Results of the recent elections indicate a reaction to the socialistic trends in our national government. A healthy state of affairs in the business world following the war will obviate any need for completely socializing medicine in America.

AGGLUTININS AID DIAGNOSIS

Discovery of substances in the blood, called cold agglutinins, that may help to segregate some of the cases of atypical pneumonia prevalent these days is announced by Dr. Oster L. Peterson, Dr. Thomas Hale Ham and Dr. Maxwell Finland, of Harvard Medical School and Boston City Hospital (*Science,* February 12).

These now prevalent kinds of pneumonia are generally called atypical pneumonia, because the disease is different from the pneumonia caused by the pneumococcus germ and is not caused by any known pneumococcus. Some cases may be caused by a virus. Until germs causing the atypical pneumonias are definitely known, the development of the cold agglutinins in the patient's blood may, the Harvard scientists suggest, serve as a criterion for segregating them.

Cold agglutinins, or autohemagglutinins as they are also called, develop very rarely in ordinary pneumonia and have been observed in a few patients with liver or blood diseases. The word cold describes the temperature at which the agglutinins act and does not refer to the common cold. The only infectious disease besides atypical pneumonia in which they have been found regularly is African sleeping sickness, known medically as trypanosomiasis.—*Science News Letter,* February 27, 1943.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

ACTION IN CHICAGO

Medical society officials all over the country are now awake to the fact that the old, comfortable, laissez-faire policy, punctuated by occasional routine blasts at the evils of state medicine, will no longer serve to protect American medicine. Nor will it keep pace with adjustments demanded by the changing times.

Evidence of this awakening was ample at the Chicago meeting of the National Conference on Medical Service, held at the Palmer House, Sunday, February 14.

It is interesting to note that Dr. W. L. Burnap of Fergus Falls was Secretary in charge of the program for the Conference and was elected President for 1944. Some thirty-five officers and members of the Minnesota State Medical Association attended the meeting.

Unforseen and almost unimagined difficulties were confronting all of the men who met there that Sunday.

They were all of them exerting every effort, out of limited supplies of physicians, to meet Army and Navy needs for medical officers. They had all been forced to decide among their colleagues who was essential and who was not to the medical service of the people at home. They were confronted with unprecedented demands, in the name of the war emergency, to let down the bars against physicians of doubtful education and background. They were face to face with a grave threat to medical education by the virtual assumption of control by the Army over the medical schools. Before them for immediate consideration were many proposals for expansion of the social security act to cover medical and hospital services. Some were engaged in prepaid medical service plans of their own. These plans were designed to meet and forestall the threat of government medicine but, so far, none had been conspicuously successful either as a public service or as a business venture. All were aware of the gradual encroachment from many avenues upon what once was the sphere of the private practitioner.

Behind the excellent formal program was the intent of its sponsors to focus and give expression to a feeling that obviously animated all of them—a feeling that the time for pronunciamentos is over and the time for concerted action is here.

This feeling resulted in unanimous passage of the following resolution for presentation to the Board of Trustees of the American Medical Association and to the House of Delegates of the Association next spring.

Resolution

WHEREAS social and economic changes have altered the lives of our citizens, and the Federal Government has found it necessary to issue directives from time to time, we as physicians believe that it is our duty to take a more active part in the creation of such regulations as affect the practice of medicine.

THEREFORE, BE IT RESOLVED, that this National Conference on Medical Service go on record as favoring the immediate development of a stronger national economic and legislative policy governing the practice of medicine and that such a policy be integrated with each state and county.

BE IT FURTHER RESOLVED that the expression of this National Conference on Medical Service be submitted to the Board of Trustees of the American Medical Association, advising them that this resolution, or a similar one, will be submitted to the delegates of the American Medical Association at their next annual meeting.

New Policies

As a result, it is hoped, an era of realistic, practical public policy will eventually replace the inaction of the past, a policy which will take into account, on the one hand, expanding conceptions of social security and on the other, the necessity for immediate steps to guide all legis-

lation and regulation impinging upon health and the medical care of the people.

History is made, these days, by directives from a bureaucrat's pen. It is only the part of wisdom and common sense that alert, forward-looking representatives of the medical profession should be at hand and in a position to offer counsel before, not after, such orders are signed and the regulations circulated.

That sort of coöperation with government agencies is not obstructive. On the contrary it represents the best type of constructive assistance which medicine can offer for the preservation of its own standards and for extension of the best possible service to all the sick.

NEW JERSEY PLAN

The Medical-Surgical Plan launched by the Medical Society of New Jersey in July, 1942, is unique in one respect.

It renders both medical and surgical care to subscribers and dependents while they are in the hospital. Thus it retains the protective feature of limiting service to the period of hospitalization and, at the same time, comes closer, in the opinion of many professional, lay and actuarial authorities, to filling the qualifications for a successfully prepaid insurance plan than do most of its contemporaries.

It coöperates closely with the Hospital Service Plan of New Jersey and has had the interest and support of many lay agencies and officials.

Members of employed groups with their dependents are eligible to participate in benefits. Premiums and requirements are simple. For single persons the service costs 75 cents a month; for subscribers with dependents, $2.00. Payment for maternity care and tonsillectomies is not allowed in the first eleven months of the first contract year. Otherwise, virtually all bills which involve hospitalization are eligible for payment.

Says Dr. Norman M. Scott, medical director and secretary of the New Jersey Society, in a recent issue of the New Jersey Journal: "Looming before us even now is the possibility of an almost unbelievable social and economic upheaval which will vitally affect the medical profession during the reconstruction period . . . .

"If such changes do come about and the medical profession is to become adjusted to them to the best advantage of our people, the profession and the practice of medicine we must first have common understanding of the problem and the united will to accomplish the adjustment. But this, alone, will not be sufficient, even though the profession be motivated by the highest purpose. For without proper technical and administrative knowledge and without an administrative agency through which we may accomplish the necessary adjustment our effort may fail. To become such an agency, to serve the profession in such a capacity is the highest purpose of a voluntary medical service corporation."

IN THE HOPPER

Signs of the times in Washington: A vocational rehabilitation bill has been introduced by Senator LaFollette of Wisconsin in the Senate and by Representative Barden of North Carolina in the House of Representatives. The bill provides for re-education and physical restoration and repair for veterans disabled in the present war, for civilian defense workers and for any other individual over the age of 16 who is disabled by reason of any physical defect or infirmity, whether congenital or acquired by accident, injury or disease. Creation of a rehabilitation service under management of a Director of rehabilitation would be created in the Federal Social Security Agency and funds would be allotted for the purpose to states presenting plans approved by the Federal Social Security Administrator. Full cost of rehabilitation for veterans would, of course, be assumed by the Federal Government. For others, the states would contribute one third.

For Extending Social Security

Six bills have already been introduced in the House and two in the Senate calling for expansions of various sorts in the Social Security Act. Provisions for disability benefits and for rehabilitaation to beneficiaries figure in several of them; but the bill introduced in the Senate by Senator Green of Rhode Island probably includes most of the items known to have the approval of the Social Security Board. It calls for extension of coverage in old age and survivor's insurance, for benefits to totally and permanently disabled workers, together with needed medical, surgical, institutional and rehabilitation services. Also for hospitalization benefits and federal aid to states for public assistance. Hos-

pitalization benefits would be not less than $3.00 a day nor more than $6.00, to be determined by the Social Security Board and to be available in institutions accredited by the Board.

Senator Wiley of Wisconsin, on the other hand, has proposed to establish a joint committee to be composed of members of the Senate Finance Committee and the House Committee on Ways and Means for the purpose of studying the need for and advisability of modifications or enlargements of the social security program and for consideration of proposals submitted to Congress therewith.

"Medical Services" of the Surgeon General

The bill for reorganization of the United States Public Health Service first proposed at the request of the Federal Security Agency in the last session has been reintroduced by Senator Thomas in the Senate and by Representative Bulwinkle in the House. By this reorganization, all functions of the public health service would be assigned to the office of the Surgeon General, to the National Institute of Health and to two bureaus, one of which would be a Bureau of Medical Services and the other a Bureau of State Services.

Obviously, a bureau on medical services within the United States Public Health Services marks a departure in policies and functions of that service. Even though the medical services provided may be definitely limited at the present time, the structure will be set up and ready to function if and as federal services expand to include care of the sick.

Cancer Clinics

In this connection, it is significant that a bill has just been introduced in the House by Representative Rogers of Massachusetts to authorize a federal appropriation enabling the United States Public Health Service to assist states, counties, cities or other political subdivisions to extend and improve measures through public and private institutions and organizations for the diagnosis, treatment and control of cancer. The bill contemplates establishment of hospitals, diagnostic, clinical and other facilities for the diagnosis and treatment of persons suffering from cancer. Funds would be allotted to states in the same manner as in plans for control of cancer under the Act of 1937, with approval of the Surgeon General.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

United States District Court Enjoins Interstate Shipment of Abortifacient Paste Manufactured by White Bear Lake Concern

Re United States of America v. Anne M. Jenks, doing business as Dependon Products and Jenks Physicians' Supplies.

On January 19, 1943, the Honorable Robert C. Bell, United States District Judge for the District of Minnesota signed an order granting a permanent injunction enjoining the shipment in interstate commerce of a drug labeled "Intrauterine Paste" or "Dependon Products Paste" manufactured and sold by Anne M. Jenks and Jenks Physicians' Supplies, White Bear Lake, Minnesota. The injunction followed a trial that commenced on January 5, 1943, at St. Paul, Minnesota. At the trial the Government called forty-six witnesses, thirty-nine of whom were physicians. Of this number six were confessed criminal abortionists and a dozen or more were physicians who had used the paste in so-called therapeutic abortions. A number of the witnesses gave expert testimony on the results that followed the use of this paste. Among the outstanding witnesses for the Government were: Dr. Anton J. Carlson, Professor Emeritus, and former Chairman of the Department of Physiology, University of Chicago; Dr. John L. McKelvey, head of the Department of Obstetrics and Gynecology, University of Minnesota; Dr. John W. Harris, head of the Department of Obstetrics and Gynecology, University of Wisconsin, and Dr. Ernest Grafenberg, obstetrician and gynecologist, New York City. The testimony of these witnesses presented a strong case that the paste is unsafe and dangerous to health.

The Court, in its findings of fact, found that the paste as shipped in interstate commerce was "composed mainly of potassium soap or other soft soap base, with small quantities of alcohol, iodine and distilled water added * * *." The Court also found that the paste was represented to the medical profession and others as being "safe and appropriate for introduction into the pregnant uterus, for the purpose of inducing labor, terminating pregnancy, and removing the retained portions of the products of conception." The Court also found that the paste was represented as "an effective medicament for the treatment of cervicitis, endometritis, dysmenorrhea, and cervical and uterine discharges." As a result of the evidence, the Court found that the paste "is unsafe and dangerous to health and has caused fatalities and serious injury. Among the specific dangers which are involved in and have resulted from its use are the extensive destruction of tissue, hemolysis or the destruction of the cellular portions of the blood, systemic potassium poisoning, extensive hemorrhage and prolonged bleeding, sterility, peritonitis, pulmonary embolism, damage to kidneys, liver and other internal organs, and increased susceptibility to infection." The Court then found as a matter of law that the paste was misbranded and that its labeling was false and misleading and that "in truth and in fact it is ineffective for such purposes." (Referring to the treatment of the conditions above enumerated.)

The Government was represented at the trial by Victor E. Anderson, United States Attorney, and Stanley V. Jacobson, Assistant United States Attorney, Mr. Jacobson doing the actual trial work. The preliminary investigation was conducted under the direction of J. O. Clarke, Chief, Central District Food

and Drug Administration, Chicago, Ill., assisted by the inspectors at the various stations throughout the United States, these men interviewing the various users of this paste. Dr. Ralph W. Weilerstein, Medical Officer, Food and Drug Administration, Washington, D. C., and Joseph L. Maguire, attorney, Office of the General Counsel, Federal Security Agency, Washington, D. C., assisted in the interviewing of medical witnesses and the legal preparation of the case for trial. Both Dr. Weilerstein and Mr. Maguire were present throughout the trial.

The Minnesota State Board of Medical Examiners wishes to commend the Government and the various governmental officers who handled the case. Many months were spent in preparing the case for trial. The success attained is a tribute to the careful preparation of the case and the superb manner in which Mr. Jacobson did the actual trial work. The defendant was represented by able counsel, but at the conclusion of the Government's case, the defendant offered no evidence and agreed that a permanent injunction should be entered on the basis of the Government's evidence.

The Minnesota State Board of Medical Examiners wishes to caution all of the members of the medical profession of this State against the use of this, or any other similar paste. Various articles have appeared in the *Journal of the American Medical Association* and elsewhere pointing out the dangers that arise from the use of an abortifacient paste. Certainly, a physician who uses such a paste, after all the warnings that have appeared, subjects himself to a grave responsibility in his relationship to the patient. While it is true that the paste was undoubtedly used by some physicians in therapeutic abortions, it is also a fact that the product was used by persons engaged in the performing of criminal abortions.

Minneapolis Woman Sentenced For Obtaining Morphine By Fraud And Deceit

Re State of Minnesota vs. Kathrine Rosenow, alias Kathrine Burkhardt, alias Kathrine Mahoney, alias Kathrine Fairchilds, alias Mrs. A. R. Fairchilds, alias Mrs. Johnson, alias Mrs. Peter Barnes, alias Mrs. Peter Varnes, alias Katherine Berg, alias Mrs. H. Peschkie.

On December 18, 1942, Mrs. Kathrine Rosenow, 2905 Irving Avenue South, Minneapolis, forty-one years of age, was sentenced by the Hon. Frank E. Reed, Judge of the District Court of Hennepin County, to an indeterminate term in the Women's Reformatory at Shakopee. Mrs. Rosenow had pleaded guilty on November 25, 1942, to an information charging her with obtaining morphine by fraud, deceit, misrepresentation and subterfuge. Mrs. Rosenow also pleaded guilty to three prior convictions of felonies for a similar offense, and is subject to a maximum sentence of life imprisonment under the laws of Minnesota. Judge Reed stayed the sentence pending the further order of the Court, and three days later, on December 21, 1942, Mrs. Rosenow was adjudged an inebriate by the Probate Court of Hennepin County, and ordered committed to the Willmar State Hospital for treatment for her drug addiction.

Mrs. Rosenow has a long record of drug addiction and numerous convictions arising out of that condition, in addition to the four felony convictions. In the present case the defendant obtained a prescription for morphine from a Minneapolis physician under a false name. The case was investigated by the Federal Bureau of Narcotics and an agent of that Department signed a complaint against the defendant. Mrs. Rosenow has gone from one physician to another in Minneapolis in her attempts to obtain morphine. Some physicians prescribed it for her and others refused. The medical profession should absolutely refuse to prescribe or dispense any of the derivatives of opium to a patient such as Mrs. Rosenow. Her prime purpose in securing morphine is to satisfy her drug addiction, and it is a criminal offense to furnish any of the derivatives of opium to a patient for such a purpose. Under the law, Mrs. Rosenow will be confined at the Willmar State Hospital until the Superintendent of that institution is of the opinion that she may be discharged. Her case will then be taken up in the District Court of Hennepin County for further proceedings under the sentence imposed by Judge Reed.

RED BLOOD CELLS SALVAGED

Red blood cells, formerly a waste by-product in the preparation of blood plasma, are now being salvaged. A saline solution of the red cells from blood collected by the Red Cross for the armed forces is being distributed in Detroit to eight Wayne County hospitals, to supplement direct transfusions or use of blood in "banks."

Detroit, among the thirty-one blood donor centers of the Red Cross in the United States, is the first to use the red blood cells, according to Dr. Warren B. Cooksey, technical supervisor of the Detroit center. While the thirty-one Red Cross blood donor centers have provided more than 1,500 000 pints of blood plasma for the treatment of armed forces and others, a paradox in the situation has been that, except on a very small scale, the red cells have been separated from the plasma and thrown away, although it is these cells, traveling in millions in the blood, which distribute to all tissues the oxygen they require.

The function of blood plasma, administered to patients, is to restore volume to the circulatory system. Without this volume the remaining blood cells and those being manufactured in the bone marrow cannot circulate.

Blood plasma is prepared for preservation over long periods. No means have been discovered for preserving and shipping red cells in the same manner, but when these cells are put in some favorable solution they can be used within one week after the blood has been drawn from a donor.

Three months ago the Detroit center undertook the preparation of this solution, saving all red cells instead of treating them as waste, and less than a month ago delivery of the solution was undertaken to nearby hospitals.

"This means that the blood banks in these hospitals may be tremendously supplemented," Dr. Cooksey said. "In any general hospital from 50 per cent to 60 per cent of patients needing new blood, either by direct transfusion or from the blood bank, are clearly cases in which the red cell solution serves just as well as the transfusion of bank blood. All red cell solutions are typed, as in direct transfusion blood or that preserved in blood banks.

"Red cells are universally needed in anemia cases. In cases of shock, only blood plasma is needed, for in shock, plasma, the fluid element of the blood, is rapidly absorbed by the body tissues. Use of the red cell solution has proved to be a remarkable aid in the treatment of various types of anemia."—*Science News Letter*, February 27, 1943.

INDUSTRIAL HEALTH

INDUSTRIAL ABSENTEEISM

Recently we have heard a great deal of the problem of industrial absenteeism—of which one of the greatest causes is sickness. The significance of the problem is illustrated by a bit of homely verse from Poor Richard's Almanac:

> "For the want of a nail, a shoe was lost,
> For want of a shoe, a horse was lost,
> For want of a horse, a rider was lost,
> For want of a rider, an army was lost,
> For want of an army, a battle was lost,
> For want of a battle, a kingdom was lost,
> All for the loss of a ten penny nail."

The man—and—machine power of this country is the ten penny nail in today's drama of war. If our productive capacity does not deliver the goods for the United Nation's battle, the poem may read: "For want of a battle, a free world was lost."

Wiley Saboteurs

All the delays from supply shortages, bottlenecks, labor troubles and sabotage combined will scarcely total in a year the destructive power of our wiliest saboteurs—disease and injury—which operate night and day in every plant in the nation. On an average of 400 million days are marked off every year due to these causes.

Bringing that astronomical figure down to earth, if *all* disabling sickness and accidents struck tomorrow in our war industries, we would cease production for the next 66 days.

It is difficult to overemphasize the seriousness of a report that in a recent month 8.5 per cent of the available labor time in a large copper mine was lost due to absenteeism.

In War Industries

There is no statistical information available to indicate the general extent of absenteeism in the war industries. Scattered reports from a number of factories reflect rates ranging from between 2 and 3 per cent up to 15 per cent and more. There also are no exact figures as to what part of this time lost is voluntary and what part is unavoidable. In certain industries in which there are extensive medical programs and close absence-control programs, it generally has not been possible to reduce absenteeism below 2 to 3 per cent. Some such level may perhaps be taken as a practical minimum and everything over this regarded as probably preventable and so, in a sense, voluntary. These national figures are quite high compared with individual plant experiences in this State.

Monday Absentees

Industrial absenteeism follows a rather marked pattern related to certain days of the week, suggesting a considerable voluntary factor. In general, absences are less frequent on paydays and quite high following payday. Moreover, there is a tendency for absences to be numerous on days adjacent to a week end or holidays. As an interesting example of this, in a certain plant over a period of several weeks, the absence rate on Friday paydays was about 4 per cent and on Mondays following payday almost 11 per cent.

There are, however, definite factors during a war effort which increase sickness and unavoidable lost time. As working hours are increased to the limit, the worker is under increasing nervous and physical strain. If the limit of his endurance is approached, time off the job in which to recuperate becomes a physiological necessity.

As the demands for labor become more acute, less nearly perfect physical specimens must be employed. More women and older employes, who have higher sickness rates, must be added to the payrolls.

In further analysis of the causes of industrial absenteeism, it has been shown in studies conducted by the American College of Surgeons that nonindustrial illness and injuries cause fifteen times as much lost time as industrial accidents. This indicates that more effort should

be devoted to reducing these causes, but does not indicate that we should let down on efforts to reduce industrial accidents. It has been estimated that illness costs labor and industry 5 billion dollars annually, and that accidents cost another 5 billion dollars.

Common Cold Leads

The common cold is still the leading cause of illness among industrial workers, accounting for about 43 per cent of lost time due to illness. The cost of the cold to the worker, calculated on salaries lost at $4 per day is about 150 million dollars annually. With added medical costs, this is about 250 million dollars per year.

The question then arises: How much of this illness is preventable? The U. S. Public Health Service and the Subcommittee on Industrial Health and Medicine says 20 per cent. The experience of 2,064 plans in the National Association of Manufacturers shows that by a proper industrial health program the application of preventive medicine, industrial absenteeism can be reduced 29.7 per cent. This means then that at least 80 million man days can be saved annually, or time enough to build 14,000 bombers, 10 dreadnaughts, or 33,000 tanks.

Such an industrial health program requires close coöperation between employers, employes, governmental health and labor agencies, and organized labor; and also between such professional groups as physicians, dentists, nurses, industrial engineers, chemists, and statisticians.

Must Protect Himself

The individual must be led to realize that to a large extent he must protect himself against disease by his own conduct, such as by securing adequate rest, proper recreation, and adequate nutrition. He should on first sign of illness consult with the medical department and should have periodic physical examinations to detect early signs of oncoming disability before it becomes chronic and incapacitating. Industrial dermatitis, one of the most bothersome of occupational diseases, can largely be prevented by careful cleansing of the skin, using proper skin cleansers. Personal protective devices such as respirators, protective clothing, and goggles, should be worn when they are provided. Finally, all workers should contribute their part in the maintenance of good plant housekeeping.

—L. W. Foker.

WOMAN'S AUXILIARY

Mrs. Raymond J. Josewski, *President*
Stillwater, Minnesota
Mrs. W. H. Rucker, *Publicity Chairman*
Minneapolis, Minnesota

St. Louis County

Mrs. W. N. Graves of Duluth was hostess to the St. Louis Medical Auxiliary on February 9 at a Valentine Bridge Party.

Goodhue County

Mrs. R. J. Josewski was guest at the January meeting held at the home of Mrs. R. V. Sherman, State Public Relations Chairman. Mrs. Josewski spoke to the group on the various ways of being of service to the community.

A Course in Nutrition was started by Mrs. E. H. Jeurs, former Home Economics instructor. This course is to be continued as a regular part of each meeting for the remainder of the year.

Scott-Carver

In Memoriam

Cordelia Pond Wunder, who died in November, 1942, took an active interest in both the State Medical Auxiliary and the Auxiliary of Scott-Carver Counties when she lived in Shakopee.

Cordelia Pond was born in Shakopee, July 2, 1885, the daughter of E. Judson and Minnie Markus Pond, and granddaughter of Rev. Samuel Pond, the well-known pioneer Presbyterian missionary among the Indians in the early days of Minnesota history. She grew to young womanhood in Shakopee and after her graduation from high school took up the profession of nursing. She took her training at Abbott Hospital and later as technician at Swedish Hospital in Minneapolis and was employed in Minneapolis, Denver and at the state sanatorium at Cannon Falls, until 1927. That year she came as laboratory technician to Mudcura Sanitarium, there to meet and become the life partner of Dr. Henry E. Wunder, physician at Mudcura.

She was a member and held office in the Minnesota State Medical Auxiliary. Shortly after her marriage she became a member of the Booklovers' Club of Shakopee and has served as its president and its secretary. The members of the club in a body were present at the funeral.

Hennepin County

On February 5 the Hennepin County Auxiliary met in the medical lounge of the county society in the Medical Arts Building.

Two delightful books were reviewed by Mrs. Boardman. During the tea hour which followed Mrs. Angus Morrison, head of the Hennepin County Red Cross, appealed to the group for more help in making Red Cross dressings as the army and navy were tripling their demands.

Minnesota Academy of Medicine

Meeting of December 9, 1942

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 9, 1942. Dinner was served at 7 o'clock and the meeting was called to order at 8 o'clock by the President, Dr. Martin Nordland.

There were forty-five members and one guest present.

Minutes of the November meeting were read and approved.

The following officers were elected for 1943:

President—Dr. H. B. Zimmermann.....Saint Paul
Vice President.....Dr. Walter Camp, Minneapolis
Secretary-Treasurer..Dr. E. V. Kenefick (reëlected)

The scientific program followed.

Dr. H. E. Michelson, of Minneapolis, gave a lantern slide talk on Clinical Reports of Cases of Tuberculosis of the Skin.

INTENSIVE CHEMOTHERAPY IN EARLY SYPHILIS

FRANCIS W. LYNCH, M.D.
Saint Paul, Minnesota

Though the clinical features of syphilis had long been known there was no really effective form of treatment until 1910. Both iodides and mercury had been applied with a degree of success and other drugs were also in use but none of these measures adequately controlled the early infectious stage. Ehrlich's introduction of chemotherapy thus opened the modern era in treatment of this disease, and he and the profession hoped that he had achieved his goal of a "therapia magna sterilisans." The clinical results of treatment were soon reported by Wechselman who recognized that repeated injections of arsphenamine were necessary in most cases of early syphilis. Thus it became evident that Ehrlich had failed to develop a drug which might cure the disease in a single injection though clinical experience soon demonstrated that he had discovered a therapeutic agent far more effective than any known before. In those early years many syphilologists developed individual schemes of treatment of early syphilis but the "Pollitzer method" may be cited as a fairly characteristic example. On three consecutive days he administered 0.1 gm. of arsphenamine for every 25 pounds of body weight and followed this intensive treatment with a series of eight weekly injections of mercury salicylate. This and similar methods of "abortive cure" remained popular for several years although 1917 saw the introduction of alternating courses of arsenical and mercurial drugs for a continuous period of one year, a routine which was not greatly changed by the later general replacement of mercury by bismuth nor by the addition of mapharsen in 1933. The method was modified in details but the principle has remained and it now represents the "standard" form of chemotherapy of early syphilis which is applied according to a more or less fixed schedule.

The results of treatment by the standard method have been generally satisfactory though cure does not always follow. Failure usually results from unwillingness or inability of the patient to complete thee entire course of treatment. The cost and discomfort, but most of all the nuisance of weekly injections keep a majority of infected persons from obtaining full benefit from treatment. These incompletely treated patients form perhaps the most important source of transmission of this disease because infectious relapse so often develops in a patient who thinks he is cured, stops treatment, then unknowingly transmits the disease to others. With arsenic as with most of the effective therapeutic agents, toxic and unpleasant reactions are fairly common but a fatal outcome is relatively rare. It is thus clear that standard methods of treatment of early syphilis are not entirely satisfactory and one can understand the reason for continued attempts to develop a quick or "abortive" cure.

Modern intensive chemotherapy in early syphilis dates from the discovery that large amounts of fluid and large doses of drugs, antigens or antibodies can be administered safely if the rate of administration is sufficiently slow. Chargin, Leifer and Hyman applied this technique in the administration of neoarsphenamine to twenty-five patients with early syphilis, giving an average of 4.0 grams in four or five days. The results were sufficiently promising so that hospital and public health authorities gave support to application of the treatment to a larger series of patients. After eighty-six additional patients were treated with neoarsphenamine the group decided to substitute mapharsen because of its lesser toxicity. The daily dose was at first selected in proportion to that of neoarsphenamine but it was soon found that larger doses could be given safely. One hundred and fifty-seven patients were then treated with an average of 700 mg. of mapharsen, an amount now regarded as inadequate, after Chargin, Leifer and Hyman increased the dose to 1200 mg. given at the rate of 240 mg. on each of five consecutive days.

Toxic reactions were to be expected in a method of treatment combining rapidity of administration and large total dosage, but they have been few and most have not been severe. Nausea, vomiting, chills, high fever, nitritoid reactions and hepatic damage have been observed infrequently. Toxic cutaneous eruptions are seen but severe types of dermatitis have been extremely rare. Aplastic anemia and related dyscrasias have not been reported. On the other hand, the intensification of administration of arsenic has led to an increase in toxic

From the Division of Dermatology, University of Minnesota, Dr. H. E. Michelson, Director.

reactions in the nervous system, a tissue not often harmed by standard therapy. Severe neuritis was frequent in cases treated intensively with neoarsphenamine but the change to mapharsen largely eliminated this unpleasant complication. The principal source of discouragement with intensive therapy has been the too frequent development of severe toxic damage to the brain. Arsenical encephalopathy, formerly and usually incorrectly described as hemorrhagic encephalitis, accounts for almost all the reported fatal reactions to intensive therapy. In most cases this reaction gives little or no warning but manifests itself several days after stopping treatment. The development of headache during the treatment signifies that administration of the drug should be stopped and hypertonic solutions should be given. Sedation is also supposed to help patients who have toxic cerebral reactions; other treatment is of little avail. The original group of New York physicians reported their series conservatively and with specific comment that they regarded the study as experimental.[7]

In spite of toxic reactions, the reported results of intensive treatment were sufficiently encouraging so that other clinicians wished to extend the use of the method. From this desire there developed a coöperating group of Midwest Clinics who have worked with the assistance and supervision of the United States Public Health Service and the Health Departments of various states. Representatives of these clinics have met regularly to review the results of the work at each clinic and to discuss the problems arising in their experiences.

Since it would have been unwise as well as impractical for all to limit themselves to the dosage and technique of the original workers, many modifications have been suggested relating chiefly to differences in dosage and technique,[5] concurrent or subsequent use of bismuth,[3a] subjection of the patient to a second course of treatment or combination with fever therapy.[1,6] Treatment has also been administered to patients having later manifestations of syphilis, a field which lies outside the scope of this presentation.[3b]

Evaluation of the results of treatment of syphilis is always difficult because the nature of the disease requires that patients should be followed for a lifetime. It is even more difficult to compare the results from intensive therapy with those obtained by standard measures because of the frequent problem of reinfection in patients treated by intensive methods, easily confused with relapse or recurrence. In most reported cases it is impossible to meet the strictest criteria of definition of infection. Certainly, reinfections should not be classed as failures but the doubtful cases provide a group which it is impossible to classify to the satisfaction of both the proponents and opponents of intensive methods of treatment.[3c] Nevertheless, a summary of results is necessary and the figures can be accepted as nearly, if not entirely accurate.

Various observers have reported cures in 83 per cent of patients with early syphilis treated continuously for six to twelve months with standard therapeutic measures. Moore has stated his belief that 95 per cent of full coöperative patients can be cured "with the best available conventional methods of treatment," but it is obvious that most patients do not receive treatment which measures up to this standard. In comparison, experience indicates that at least 85 per cent of early cases can be cured by the "New York technique" of intensive therapy.[3d] If patients who fail to respond and those who have relapses are given the advantage of a second course of treatment the results can be considerably improved.

Results of Treatment at University Hospitals

At the University Hospitals treatment has been given only to patients with early syphilis and the standardized method of Chargin, Leifer and Hyman has been followed. Although the series of patients is not large, it may be of local interest to review the results.[4] All patients had early syphilis and were treated with the generous cöoperation and help of the Minnesota Department of Health. Included in the report are thirty-seven cases, eighteen of them men and nineteen women. The majority were between twenty and thirty years of age, eight being younger and five older than those limits. The course of treatment has usually been uneventful; twenty-five patients had no distressing reaction. Of the remainder, four had fever of more than 102 degrees but no other evidence of toxicity. One of these and one other patient developed "erythema of the ninth day," an eruption whose significance is not clear but which is also seen in patients treated by standard methods and is not regarded as evidence of major toxicity. One developed pain in the arm, probably vascular rather than neuritic in nature. Two had mild toxic eruptions of the type which does not go on to exfoliation and dermatitis.

All the reactions so far listed can be regarded as mild and of no consequence; similar reactions might be met with in a series of patients treated by standard methods. Unfortunately, it is necessary to add a record of two deaths, associated with signs and symptoms of cerebral involvement (arsenical encephalopathy). In neither case had there been any untoward incident during the course of treatment; the symptoms developed several days later and led rapidly to unconsciousness and death. Both patients were in excellent physical condition previous to acquiring their syphilis which had progressed to the stage of a generalized eruption when treatment was begun.

Two fatal reactions in a series of thirty-seven cases is extremely discouraging and no further consideration can be given so toxic a therapeutic modality, regardless of how good the results may have been in the thirty-five remaining patients, unless experience of others is more favorable. Reports from other clinics show that the local series is not a fair example of what may be expected with intensive treatment. A few fatal cases have been observed by others but the number is small and it is evident that the mortality rate with the "New York dosage" must be approximately 1 in 250 to 300. This mortality rate must first be balanced against the effects of the disease when untreated; from this viewpoint use of the method is fully justified. The mortality rate must also be compared with that of standard

methods of treatment and here one runs into major difficulty; one cannot give even a close approximation of the mortality rate for the standard treatment of syphilis. The clinician's memory is notoriously inaccurate when he is asked to recall from his experiences deaths resulting from treatment. Records are not satisfactory for many reasons, one being that death so often occurs in a different community or at least a different hospital and clinic from that where the offending treatment was administered.[3e] It can only be stated that the risk of death is greater with intensive than with the standard methods and that clinicians of experience disagree within wide limits as to the proportion of increased risk.

In reporting the results of treatment in the local series it is impossible to speak of "cure" because insufficient time has passed; results can only be classified as satisfactory from the standpoint of serologic reversal, maintenance of negativity and absence of clinical evidence of infectious relapse. Four of the thirty-seven cases were treated so recently that the last observation was made less than six months after completion of the course of treatment; they are excluded from consideration in this part of the report. Spinal fluid examination at the end of one year has demonstrated no positive reactions in twelve cases; one patient whose fluid was abnormal before treatment, later had a normal fluid. In the remaining cases the fluid has not yet been examined. No clinical evidence of relapse has been demonstrated in any case but not all have had the benefit of frequent and thorough examination.

Because most physicians in this community depend chiefly on results of the Kolmer test as performed by the laboratory of the Minnesota Department of Health, the result of this test has been regarded as the criterion of serologic status. In all cases numerous other tests have been performed including quantitative estimates in Dr. Kahn's laboratory at Ann Arbor. Of thirteen patients observed twelve or more months after treatment, eleven gave negative reactions to the Kolmer test (85 per cent). In the two remaining cases the reaction was positive but decreasing in titre according to Dr. Kahn's report;[3f] these two patients had generalized eruptions when treatment was started. Among eighteen cases where the last test was performed six to twelve months after treatment the Kolmer reaction was positive in two. Regarding as failures the two cases in each of these groups and the two having fatal reactions, the results of treatment were satisfactory in twenty-five of thirty-one cases (81 per cent). The favorable results in this small series are comparable with those in the composite report of the Midwest Group of Clinics.

Comment

I believe that almost all dermatologists agree that the present degree of success with intensive therapy of early syphilis completely justifies continuation and modification on an experimental basis searching for a less toxic but equally effective method. Most will agree with Wile's statement that the introduction of this form of treatment is a milestone in the development of antisyphilitic therapy.[3g]

Where is the future of intensive chemotherapy of early syphilis? The most promising modifications are administration of a second course of treatment in cases where a single course appears to have failed, the combination of less intensive arsenical therapy with concurrent or subsequent courses of bismuth or the concurrent administration of fever therapy. The two latter methods offer the advantage of decreasing the amount of arsenic and thus lessening the likelihood of toxic reaction. Even if changes in intensive therapeutic methods fail to bring the results we all hope for, the introduction of this method has served many advantageous purposes. It has attracted public attention to the important problem of controlling syphilis. It leads to hospitalization of patients in the most infectious stage of the disease, thus decreasing the likelihood of transmission of syphilis. It forces the patient to complete the desired course of treatment. Aside from the line of thought considered in this presentation there is the very considerable advantage that supporters of more conservative methods of treatment have been obliged to reëvaluate the results obtained with standard methods and have been stimulated to attempt to improve those methods.[2]

Summary

The modern methods of intensive chemotherapy in early syphilis have been discussed briefly with reference to the development of the technique, the results of treatment and the toxic reactions to be expected. Thirty-seven patients with early syphilis received intensive therapy at the University Hospitals; the results are reported. An apparently satisfactory result has been recorded in 81 per cent of the cases, a figure which compares with the reports of other clinics using similar methods (85 per cent). The incidence of fatal reaction was higher in the local series than it has been among patients treated elsewhere.

The advantages and disadvantages of intensive chemotherapy have been discussed briefly. Hope is expressed that a less toxic, more effective and equally rapid form of treatment may be developed.

Discussion

Dr. H. E. Michelson, Minneapolis: Dr. Lynch has given us a very good review of this new treatment of syphilis. He has not stated that we were advocates or opponents of the method, but merely pointed out the good and bad points. When one is confronted with a new treatment for syphilis, he must consider whether the treatment is a better type of treatment, whether it is safe, and, is it available? We have had no scarcity of drugs or methods in the treatment of syphilis. It has been largely a matter of how to employ the drugs offered. A biological treatment has not as yet been put forward. With any chemical, one must always consider the dosage, the dilution, the interval, and the total amount which may be given. In syphilis, it is important to realize that most patients are able either to overcome, or at least control, the infection without the aid of drugs. Therefore, one must always consider whether or not the treatment is interfering with the natural immunity process.

There is no question that the danger in this new treatment lies in the total amount of arsenic given to the patient in a very short length of time, and we feel certain that the same amount, spread over a much longer time, is not nearly as dangerous; therefore, the economic side of the question becomes important. It is hard to estimate whether it is advisable to concentrate a treatment, and thereby assume a big risk, or to spread the treatment out, with much less risk. All in all, Dr. Lynch has given you our view on the matter, and time alone will tell whether or not the treatment should be the one of choice for early syphilis.

Dr. H. Z. Giffin, Rochester: I am not sure whether 85 per cent of all patients who begin standard treatment are subsequently cured, or whether the figure is 85 per cent of those who complete treatment by standard methods. Will Dr. Lynch clarify this point?

Dr. H. B. Zimmermann, Saint Paul: Since bismuth apparently can be substituted effectively for part of the arsenic originally used in treatment and the latter is the more toxic drug, why cannot the substitution be complete and only the less toxic drug, bismuth, be used?

Dr. J. M. Armstrong, Saint Paul: When bismuth has been substituted or added to intensive arsenical therapy, in what form has it been administered?

Dr. Lynch, in closing: In reply to Dr. Giffin, the estimate of 85 per cent effectiveness with standard treatment measures is dependent on completion of the scheduled amount of treatment. Perhaps the majority of patients do not receive the desired amount of treatment and the incidence of cure is thus lowered considerably. One of the greatest advantages of intensive treatment methods lies in the fact that practically all the patients receive the desired amount of treatment.

Only in experimental animals has Tatum shown that metallic bismuth is therapeutically equal with arsenic in the same amounts; perhaps this is not true for humans. While Dr. Zimmermann's suggestion of complete substitution would lower the rate of reactions, bismuth works so much less rapidly that we would lose one of the chief advantages of intensive methods, the quick elimination of infectiousness. Bismuth and arsenic apparently do not work in the same manner in syphilis; probably the ideal treatment will use a combination of the two.

In reply to Dr. Armstrong's question, various workers have used the different forms of bismuth, aqueous solution, oily solution and suspension in oil. In experimental animals Tatum has shown that at least five of the standard forms of bismuth are equally effective.

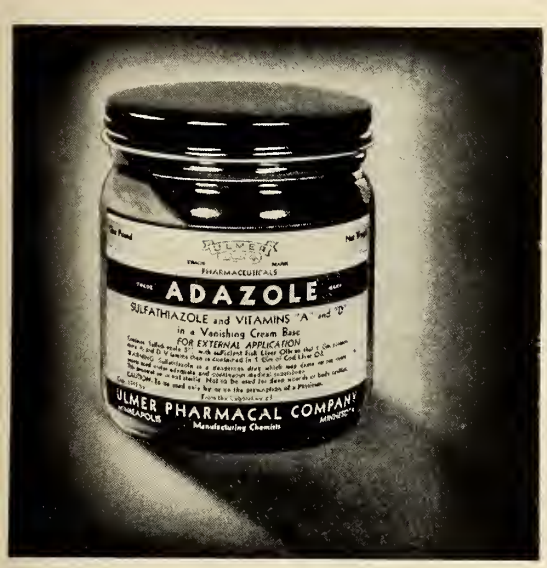
The discussers have been kind enough not to ask why our mortality rate exceeds that of other clinics. I would like to offer two excuses, admitting that even they are not sufficient explanation. The series at the University Hospitals included no Negroes; they are notoriously tolerant of arsenical therapy and comprise large fractions of the groups treated by many clinics. The proportion of women in our series is also above that usually found in clinic practice and women are less tolerant of arsenical drugs. Another fair question would relate to the need for intravenous drip therapy. The drug may also be administered in divided doses given by syringe at intervals during the day.

To summarize my own opinions relating to intensive treatment measures: I hope for an improved and safer method which may be acceptable for universal use. In the meantime, I believe the present method is too dangerous for general application but I think its use is justified in certain instances, particularly when dealing with irresponsible or transient persons who are obviously unlikely to complete the full course of standard treatment. The increased risk is justified not only by the increased likelihood of cure of the individual but also, and probably more important, by reducing the period of infectiousness and thus preventing transmission of the disease to others.

The meeting adjourned.

E. V. Kenefick, M.D., *Secretary*

---



*Thanks to books the dead appear to me as though they still lived—everything decays and falls into dust by the force of time; Saturn is never weary of devouring his children and the glory of the world would be buried in oblivion had not God as a remedy conferred on mortal man the benefit of books. * * * Books are the masters that instruct us without rods or ferrules, without reprimands or anger, without the solemnity of the gown of the expense of lessons. Go to them, you will not find them asleep; if you err, no scoldings on their part; if you are ignorant, no mocking laughter.*—Quoted from Richard de Bury (Philobiblion, 1345) in a *Surgical Pilgrim's Progress* 1845-1925, Reminiscences of Lewis Stephen Pilcher.

TREATMENT OF CRANIOCEREBRAL INJURIES IN MODERN WARFARE

(Continued from Page 287)

rents in the dura with a large skull defect, and sometimes can be covered by osteoplastic structures or by certain metals, such as tantalum and vitallium. Celluloid plates have been used with fair success, but the inert metals are perhaps more desirable. The problem of the malingerer is always a factor in the treatment of any person who has received an injury, but fortunately it does not occur so often in the military field as it does in civil practice among members of the civilian population who have compensation insurance.

FOR *Professional use* ONLY

ADAZOLE

ULMER *Quality*

SULFATHIAZOLE CREAM (5%)

Fortified with Natural Cod Liver Oil Vitamins A and D

Extensive research has long indicated the importance of cod liver oil ointments in hastening the healing of damaged tissues. With the development of the sulfonamide drugs and their amazing accomplishments in controlling infection, it was a logical move to combine sulfathiazole with cod liver oil in a suitable cream base. The result is ADAZOLE (Ulmer), containing 5% SULFATHIAZOLE, in a stainless vanishing cream base, fortified with natural cod liver oil vitamins A and D.

ADAZOLE (Ulmer) is a pharmaceutical achievement and its acceptance is general with the medical profession. It is proving especially valuable in industrial work where loss of skin tissue and abrasion presents one of the greatest difficulties in caring for employes and is a frequent cause of prolonged disability. In the treatment of this type of wound the application of ADAZOLE (Ulmer) requires much less frequent change of dressings, helps to reduce infection and aids rapid healing without destruction of the new granulation tissue.

If you haven't already learned at first hand the value of ADAZOLE (Ulmer) in treating your patients, we suggest that you include a trial jar with your next order. Per pound.....$3.00.

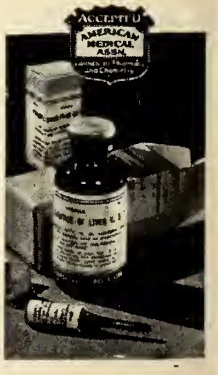
AMERICAN UROLOGICAL ASSOCIATION

The $500 Research Prize annually offered by the American Urological Association will not be awarded this year, according to an announcement received from Dr. Miley B. Wesson, chairman of the Committee on Research. As the Government has discouraged the holding of medical conventions, except those primarily of military interest, plans for the June meeting of the American Urological Association in St. Louis have been cancelled.

AMERICAN COLLEGE OF SURGEONS

The first session of a series of twenty war sessions of the American College of Surgeons to be given throughout the United States was held March 1 at the Lowry Hotel in Saint Paul.

Topics discussed relating to military medicine included care of the ill and injured in combat zones and after evacuation. The newer types of injuries encountered in this war, such as crush and blast injuries, were especially considered, together with prevention and treatment of infections, and treatment of burns, shock, and injuries of specific parts of the body. Anesthesia, plastic surgery, and the psychoneuroses of war also were discussed. Problems of civilian medical care in wartime, included the responsibilities of individual doctors and hospitals; personnel problems of hospitals; organization of emergency medical services; maintaining adequate supplies, furnishings, and equipment; maintenance of high standards of medical and nursing education, and of hospital service in general; hospital public relations; and administrative adjustments in professional staffs of hospitals. The opening meeting of the session was de-



"Recalled to Life"

LIKE a call to renewed life for the pernicious anemia patient, come the latest developments in liver therapy. . . . For intramuscular injection, Smith-Dorsey has prepared a U. S. P. voted to discussion of "Medical and Surgical Aspects of Chemical Warfare," and the closing meeting was devoted to a panel discussion on problems in wartime civilian medical practice.

The American College of Surgeons cancelled its 1942 national meeting and is holding in abeyance plans for a Clinical Congress in 1943, in the meantime offering the regional meeting plan provided by the War Sessions to save the time of the doctors and other personnel, and to minimize transportation difficulties, without sacrificing unduly during wartime the educational and stimulative benefits of medical assemblies.

E. STARR JUDD LECTURE

Dr. Alfred Blalock of Baltimore, Maryland, Professor of Surgery at the Johns Hopkins Hospital, will give the tenth E. Starr Judd lecture at the University of Minnesota in the Museum of Natural History Auditorium on Thursday, March 11, 1943, at 8:15 p.m. The subject of Dr. Blalock's lecture is "Traumatic Shock with Particular Reference to War Injuries."

The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in surgery a few years before his death.

SIGMA XI LECTURES

First of three speakers sent out by the national organization of Sigma Xi, honor society in science, who are this year taking the place of the traditional University of Minnesota speakers, appeared on the campus, Wednesday, February 10. Dr. D. W. Bronk, director of the University of Pennsylvania's Institute of Neurology, spoke in the Medical Science Amphitheatre on "The Human Machine in Aerial Warfare." His talk was given under the joint auspices of the Minnesota chapter of Sigma Xi and the Medical School. He described the exceedingly delicate means of measuring changes in nerve cells whereby the body keeps itself in balance with its environment and went on to show how these balances and other body functions are upset at the heights to which modern airplanes fly. The human body is unable through normal means to make the rapid adjustments required in the nervous system and in the blood stream and science has had to step in, with special equipment, to fill the need.

The second lecture of the series will be given under the sponsorship of the society and the Physics Department of the University, Thursday, March 10, at 4:30 P.M. in room 150, Physics Building. G. D. Birkhoff, Perkins Professor of Mathematics of Harvard University, will speak on "The Mathematical Nature of Modern Physical Theories."

On Thursday, April 1, the third lecture will be given at 8:00 P.M. in the Chemistry Auditorium under the auspices of the society and the Minnesota chapter of the American Chemical Society. Dr. Peter Debye, Professor of Chemistry of Cornell University, will present the subject "The Magnetic Approach to Absolute Zero."

ANNOUNCES CONTINUOUS COURSES

SURGERY—Two Weeks' Intensive Course in Surgical Technique starting March 8 and 22, April 5 and 19, and every two weeks throughout the year.

MEDICINE—Two Weeks' Intensive Course in Medicine starting June 7. One-month Course in Electrocardiography and Heart Disease starting the first of every month, except August.

FRACTURES & TRAUMATIC SURGERY—Two Weeks' Intensive Course starting April 5.

GYNECOLOGY—Two Weeks' Intensive Course starting April 5; Clinical and Diagnostic Courses.

OBSTETRICS—Two Weeks' Intensive Course starting April 19; Informal Course.

OPHTHALMOLOGY—Two Weeks' Intensive Course starting April 5.

OTOLARYNGOLOGY—Two Weeks' Intensive Course starting April 19.

ROENTGENOLOGY—Courses in X-ray Interpretation, Fluoroscopy, Deep X-ray Therapy every week.

UROLOGY—Two Weeks' Course and One-month Course available every two weeks.

CYSTOSCOPY—Ten-day Practical Course every two weeks.

General, Intensive and Special Courses in All Branches of Medicine, Surgery and the Specialties.

TEACHING FACULTY — ATTENDING STAFF OF COOK COUNTY HOSPITAL

Address: Registrar, 427 S. Honore St., Chicago, Ill.

REFRESHER COURSE

A refresher course in Laryngology, Rhinology and Otology will be given March 22 to 27, inclusive, 1943, at the University of Illinois College of Medicine. The course has been arranged to meet the needs of ear, nose and throat specialists who, under existing conditions, are able to devote only a brief period to postgraduate review study. Registration is limited. The fee for the complete course is $50.00. In requesting application for registration, physicians are asked to state school and year of graduation, also details concerning specialty training and experience. Correspondence should be addressed to Department of Otolaryngology, University of Illinois College of Medicine, 1853 West Polk Street, Chicago, Illinois.

CLAY-BECKER MEDICAL SOCIETY

Dr. O. O. Larsen of Detroit Lakes was elected president of the Clay-Becker Medical Society at its annual meeting held at Moorhead recently. Other Officers are Dr. G. L. Gosslee, Moorhead, vice president, and Dr. R. R. Hendrickson, Sand Beach Sanatorium, secretary-treasurer.

STEELE COUNTY MEDICAL SOCIETY

Dr. J. A. McIntyre of Owatonna was elected president of the Steele County Medical Society when members held the annual meeting at the Owatonna City Hospital the latter part of January. Elected vice president and censor for a three-year term was Dr. E. J. Nelson. Dr. D. H. Dewey was elected secretary-treasurer.

Dr. D. E. Morehead was named delegate to the State Medical Association convention with Dr. Dewey as alternate.

UPPER MISSISSIPPI MEDICAL ASSOCIATION

Dr. H. W. Lee of Brainerd was elected president of the Upper Mississippi Medical Association at the annual meeting of the organization held in February at Brainerd. Other members elected to office were: Dr. D. F. McCann of Bemidji, vice president; Dr. L. T. Davis of Wadena, second vice president; Dr. A. H. Borgerson of Long Prairie, third vice president; and Dr. G. I. Badeaux of Brainerd, secretary-treasurer.

Chosen as delegates to the State Association were Dr. B. A. Smith of Crosby, Dr. G. I. Badeaux of Brainerd, Dr. A. M. Watson of Royalton and Dr. J. A. Thabes, Jr., of Brainerd.

WASHINGTON COUNTY MEDICAL SOCIETY

The Washington County Medical Society held its monthly meeting Tuesday evening, February 9, at Stillwater. The scientific program consisted of a colored motion picture showing lesions of the lower bowel, interpreted by William C. Bernstein, M.D., of Saint Paul. Dr. Bernstein presented this difficult subject, important to all medical practitioners, in an interesting and informative manner.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE 1942 YEAR BOOK OF GENERAL MEDICINE. 848 pages. $3.00. Chicago: Year Book Pub., 1942.

This yearbook makes its usual valuable contribution to medical literature. It gives a very good review of the important advances in medical diagnosis and treatment as reported in the periodicals in 1941 and 1942 and any physician would do well to go through it carefully. The grouping of articles on specific subjects is a very helpful procedure. The percentage of abstracts of foreign literature is small in this volume, of course, but there are a number from the English, Swiss, Scandinavian and South American literature.

PSYCHOTHERAPY IN MEDICAL PRACTICE. Maurice Levine, M.D., Attending Psychiatrist, Cincinnati General Hospital; Assistant Professor of Psychiatry, University of Cincinnati, College of Medicine. 320 pages. $3.50. New York: Macmillan Co., 1942.

This is a useful and practical book. The author has put much thought and knowledge into it. His thoughtfulness is shown in the manner in which he groups his subjects and in the explanatory treatment he gives them. His knowledge encompasses the more recent psychiatric concepts. While the book is intended for the physician in general practice, it would not be out of place in the library of a psychiatrist.

FRANK H. WHITMORE, M.D.

WHEN DOCTORS ARE RATIONED. Dwight Anderson and Margaret Baylous. 255 pages. $2.00. New York: Coward McCann Inc., 1942.

This is another book for public consumption. The opening chapters attend to the title and its implications. The remaining chapters discuss relationships between doctor and patient and tend to enlighten the public mind concerning the way to go about locating or choosing a reliable physician. It discusses quacks, specialists, women doctors and how to be a good patient. At times the reader might think himself perusing the catalogue of a medical school setting forth the qualifications desirable for a medical student.

Most physicians by this time are amply conversant with the ramifications of the Procurement and Assignment Service. The book deals with this, of course, but the subject is soon exhausted and when the above subjects have been discussed under various headings the final chapters have some rather interesting comments on the subject of controlled medicine which it would be well for the lay reader to peruse and ponder.

ARTHUR N. COLLINS, M.D.

SPENCER
Breast Supports
For Pre-Natal and Nursing

Spencer Maternity Support Spencer Nursing Support

Each Spencer Breast Support for pre-natal wear, like *all* Spencer Supports, is *individually designed* for the one patient who is to wear it, to lift and hold breasts in natural, healthful position, without compression.

It improves circulation—protects delicate inner tissues—helps prevent outer skin from stretching and breaking—aids breathing—improves appearance—encourages erect posture. Easily adjustable to increasing development.

Painful, engorged breasts are often relieved by a Spencer, as it allows veins to empty easily. (A further advantage is gained later in increased milk supply from equalization of circulation during pregnancy.)

GUARDS AGAINST CAKING AND ABCESSING

The Spencer Breast Support for nursing mothers provides protection against caking and abcessing. Padded slide-fastener in front for nursing convenience.

For service look in telephone book under "Spencer Corsetiere" or write direct to us.

SOLAREUM PAPER TABLE SHEETING

The Modern, Economical Way For Progressive Physicians

Ready at the head of your examining table is a continuous, instant supply of SOLAREUM sheeting. Here, in a sanitary holder that is especially designed to fit any style of table you might have in your office, you have about 700 to 1,000 lineal feet available, quick as a flash, whenever you need it.

SOLAREUM sheeting is purposely made for efficient service in the modern physician's office. It is conveniently, quickly spread over your table, and is pleasant to lie on. There is no crackling noise, no cold feeling, no discomfort to disturb the nervous patient.

SOLAREUM sheeting is inexpensive, saving nearly all or much of the laundry cost, according to the nature of your practice. It gives you a clean sheet for each patient at minimum cost. Distributed over an entire year this saving is well worth considering.

Election of officers following the dinner, resulted as follows: Dr. F. H. Hubbe, president; Dr. C. A. Saffert, vice president; Dr. H. A. Vogel, secretary.

* * *

At the regular meeting of the Staff of Wesley Hospital, Wadena, Minnesota, in February, the following officers were elected: President, Dr. E. C. Hanson; vice president, Dr. A. J. Lewis; secretary-treasurer, Dr. Henry Silver. Dr. Thomas Ziskin of Minneapolis spoke to the staff members in January on "Electrocardiography."

* * *

Carl H. Swanson, state director of public institutions, appeared before the house appropriations committee recently and submitted budgets for four additional state hospitals and the school for feeble minded at Faribault. Special requests for the Fergus Falls institution included $15,000 for repairing and re-shingling roof and main buildings; $15,000 addition to men's buildings for tuberculous patients.

* * *

Dr. E. W. Bedford is new chief of staff of Eitel Hospital, Minneapolis, succeeding Dr. Gilbert J. Thomas. Dr. William R. Jones is new assistant chief and Dr. Alton C. Olson is secretary-treasurer. The new officers were elected at the annual meeting of the hospital staff. Principal speakers at the meeting were Dr. R. W. Backus, medical missionary recently returned from China, and Capt. Beryl Hirschfield of the Army Medical Corps.

* * *

At the annual meeting of the Bethesda Hospital Association, Fertile, Minnesota, Dr. C. L. Oppegaard of Crookston was elected a member of the Board. Officers of the Association are: Alfred Solstad, Fertile, president; O. M. Grovern, Mentor, vice president; Elmer Hanson, Fertile, treasurer and F. H. Stadsvold, Crookston, secretary. Other members of the Board are Theodore Stromstad of Beltrami and Hans Haugen of Nielsville.

Dr. William B. Roberts of Minneapolis was named new chief of staff of St. Barnabas Hospital to succeed Dr. Reuben M. Rosenwald, at the annual meeting in February. Previous to his appointment Dr. Roberts was a member of the hospital's Executive Committee. He has been associated with St. Barnabas for fifteen years and for twenty-five years was chief of staff at Eitel Hospital. He is now a member of the staffs of Eitel and Franklin Hospitals, as well as St. Barnabas. He has been a practicing physician in Minneapolis for forty years.

* * *

E. M. Hauge, superintendent of Fairview Hospital, Minneapolis, was elected president of Minnesota Hospital Service Association at a meeting held in February at St. Joseph's Hospital, St. Paul. Mr. Hauge succeeds James McNee, Duluth.

Other officers elected were: Samuel W. Pinkerton, Saint Paul, vice president; Dr. Peter D. Ward, Saint Paul, secretary; A. A. McRae, Minneapolis, treasurer; Henry Thrall, Minneapolis, assistant treasurer.

Victor M. Anderson, Minneapolis, Dr. Ward, Mr. McRae, Mother Conchessa, Minneapolis, the Rev. L. R. Benson, Saint Paul, and Abbott L. Fletcher, Minneapolis, were named trustees.

* * *

At its annual meeting held in February, the medical staff of St. Mary's Hospital, Duluth, elected Dr. F. N. Knapp chief of staff for 1943, and Dr. Richard Bardon as chief-elect for 1944. Dr. Knapp succeeds Dr. P. F. Eckman.

Other staff officers named are Dr. K. W. Emanuel, secretary; Dr. L. A. Barney, chief of surgery; Dr. S. N. Litman, chief of pediatrics; Dr. C. E. Taylor, chief of contagion; Dr. F. G. Hirschboeck, chief of neurology, and Dr. P. N. Bray, chief of obstetrics. Holdover officers are Dr. C. M. Smith, chief of medicine; Dr. E. Z. Shapiro, chief of urology; Dr. F. J. Elias, chief of orthopedics, and Dr. E. L. Tuohy, chief of laboratory.

Speakers at a dinner, which preceded the election, were Lieut.-Col. Wallace Hunt, Omaha, Nebraska, chief of medical defense for the Seventh Corps area, and Edwin A. Martini, Duluth, president of the Minnesota Arrowhead chapter of the Red Cross.

send the
cigarette that's the

FAVORITE OF THE ARMED FORCES *

FRIEND or relative—send him cigarettes—the first choice among officers and in the ranks—the gift they prefer above all others. The brand? Camels—by actual survey*, first choice of American men in war.

Slow-burning Camels have the features that service smokers want—extra mildness, smooth mellowness, better flavor—every puff.

Your dealer will gladly serve you with Camel cigarettes by the carton; see him today.

Camel

costlier tobaccos

REMEMBER, you can *still* send Camels to Army personnel in the U. S., and to men in the Navy, Marines, or Coast Guard *wherever they are.* The Post Office rule against mailing packages applies only to those sent to the overseas Army.

* With men in the Army, the Navy, the Marine Corps, and the Coast Guard, the favorite cigarette is Camel. (Based on actual sales records in Post Exchanges and Canteens.)

Some men are so clever!

Take my boss for instance . . .

Yesterday, I overheard him talking to another doctor about infant feeding.

"Jim," he said, "I'll tell you why you never have any time to spare. You get yourself tied up with a lot of unnecessary work.

"You believe in prescribing plain cow's milk modified. Haven't you found out that S-M-A* will save you a lot of unnecessary questions? Cut out a lot of bothersome arithmetic?

"Heaven knows, we're busy enough as it is. I'll bet you a couple of tickets for the big game that with S-M-A on the job—your patients won't have to telephone you so often to ask about their baby's formula."

☆ ☆ ☆

Well, you can see why I think my boss is so clever. Why don't you try S-M-A in your own practice, doctor? See if you don't like it better.

BUSY DOCTORS TODAY—PRESCRIBE S-M-A!

With the exception of Vitamin C . . . S-M-A is nutritionally complete. Vitamins B_1, D and A are included in adequate proportion . . . ready to feed. Their presence in S-M-A prevents the development of subclinical vitamin deficiencies . . . because the infant gets all the necessary vitamins right from the start.

S-M-A has still another highly important advantage not found in other modified milk formulas. It contains a special fat that resembles breast milk fat . . . resembles it chemically and physically—according to impartial laboratory tests. S-M-A fat is more readily digested and tolerated by most infants than cow's milk fat.

S-M-A IS EASIER TO PREPARE. ONE MEASURE OF POWDER TO EACH OUNCE OF WARM, BOILED WATER, COMPLETES THE FORMULA . . . TWENTY CALORIES TO THE OUNCE

The infant food that is nutritionally complete

ACCEPTED AMERICAN MEDICAL ASSN. Council on Foods

S-M-A, a trade-mark of S.M.A. Corporation, for its brand of food especially prepared for infant feeding—derived from tuberculin-tested cow's milk, the fat of which is replaced by animal and vegetable fats, including biologically tested cod liver oil; with the addition of milk sugar and potassium chloride; altogether forming an antirachitic food. When diluted according to directions, it is essentially similar to human milk in percentages of protein, fat, carbohydrate and ash, in chemical constants of the fat and physical properties.

• *Violence during grand movements is pictured by Paul Richer, one of the distinguished artists of medicine, in his Etudes Cliniques sur L'Hysterio-Epilepsie (1881).*

"A sharp edged weapon which must be used both boldly and deftly."[1]

Dilantin* Sodium (phenytoin sodium) is "recognized as the drug of choice for patients having grand mal or psychomotor seizures. Its usefulness should not be lessened just because its administration requires careful and intelligent supervision by the attending physician. Ignorance or timidity on the part of the doctor has blighted the budding hope of many a patient . . . Epilepsy is a tough disease which laughs at dull weapons."[1]

Kapseals Dilantin Sodium (phenytoin sodium) are providing new relief for many epileptic patients. With its use seizures usually decrease in number and sometimes cease entirely.

"MANPOWER" . . .
and the Menopause

"MANPOWER" in industry is rapidly changing to "womanpower." And, with so many women on production and assembly lines, the problem of absenteeism and lowered efficiency, particularly among women in their forties, deserves consideration.

It has been estimated that 80 per cent of women in this age group experience menopausal symptoms of varying intensity. Efficiency demands that these workers be physically and emotionally fit. Clinical investigations show that, in a large percentage of cases, they can be kept "on the job" through the use of adequate estrogenic therapy.

The high clinical effectiveness of Amniotin in relieving the distressing vasomotor symptoms of the menopause has been amply demonstrated by numerous clinical reports published during the past 12 years. The product has likewise proved valuable in treating other conditions related to a deficiency of estrogenic substances.

Two New Advantages . . . The new economy-size vials of Amniotin offer two distinct advantages. They provide a substantial saving over the cost of Amniotin in ampuls and they facilitate the use of fractional doses without waste of material.

Differing from estrogenic substances containing or derived from a single crystalline factor, Amniotin is a highly purified, non-crystalline preparation of naturally occurring estrogenic substances derived from pregnant mares' urine. Its estrogenic activity is expressed in terms of the equivalent of international units of estrone. In addition to the economy-vial packages and the ampuls (both of which are for intramuscular injection) you can secure Amniotin in capsules for oral administration and in pessaries for intravaginal use.

ECONOMY-SIZE VIALS	10 cc.	20,000 I. U. per cc.
	10 cc.	10,000 I. U. per cc.
	20 cc.	2,000 I. U. per cc.

Child Immunization
more essential than ever
in War Time . . .

EVERY PRACTITIONER should be on the alert to encourage immunization programs and to urge immunization in his private practice. The migration of families by the thousands, almost universal decrease in home supervision of children, increasing personal contacts throughout industry, and the relative scarcity of physicians combine to increase the likelihood of the spread of infectious diseases.

As an aid in this work Lederle offers many products of established efficacy for the production of active immunity . . .

Specify **Lederle**

IMMUNIZATION SCHEDULE		
Immunization should be carried out against:	LEDERLE PRODUCT	TIME
Smallpox	Smallpox Vaccine*	6-12 months (revaccinate at 6 and 12 years)
Diphtheria	Diphtheria Toxoids*	6-12 months (Schick Test at 6 years—reimmunize if necessary)
Rabies	Rabies Vaccine*	Promptly after exposure
Immunization is recommended against:	**LEDERLE PRODUCT**	**TIME**
Scarlet Fever	Scarlet Fever Streptococcus Toxin*	After 18 months
Measles	Immune Globulin*	After exposure
Tetanus	Tetanus Toxoid*	Before probable exposure

**Accepted by Council on Pharmacy and Chemistry of the American Medical Association.*

THE SYNDROME OF LOWNESS

LOW MUSCLE TONE, LOW BLOOD PRESSURE LOW RESISTANCE are part of a syndrome characteristic of adrenal cortical insufficiency.

Adrenal Cortex Extract (Upjohn) is a most potent specific therapy now available for alleviation of these typical symptoms, when due to adrenal cortex insufficiency. Adrenal Cortex Extract (Upjohn) is a potent natural complex representing steroids which influence carbohydrate metabolism, capillary tone, vascular permeability, plasma volume, body fluids and electrolytes. "No one of these substances and no synthetic substance has yet been shown to possess all of the effects of a potent cortical extract." N. N. R. 1942

ATYPICAL PNEUMONIA

WESLEY W. SPINK, M.D.
University of Minnesota Medical School
Minneapolis, Minnesota

CONSIDERABLE attention has been focused in recent years upon a type of pneumonia of doubtful etiology. Apparently, physicians in various parts of the country in civilian and military practice have encountered a considerable number of cases occurring sporadically and in epidemics. Failure to establish a diagnosis of bacterial origin has given rise to the terms of "atypical" pneumonia, or "virus" pneumonia. Whether or not a new clinical entity has been introduced within the last decade is not known. Reimann is of the opinion that the syndrome has occurred in the past, and its common recognition at present is due to the more frequent use of x-ray films for diagnostic purposes, the common use of precise bacteriological methods in the diagnosis of pneumonia, and the control of pneumococcic pneumonia with chemotherapy. Furthermore many of the cases of atypical pneumonia in the past may have been labelled as bronchopneumonia or capillary bronchitis.

The clinical features of atypical pneumonia appear to follow a general pattern, but there may be confusing variations from individual to individual, and also in patients in different geographical areas. The incubation period is not definitely known. The onset of illness is usually gradual with the patient exhibiting a feeling of malaise, chilly sensations and headache. In some instances, the headaches have been quite severe, and body aches and pains have been prominent complaints. Sore throats are not of particular significance. A cough may be most distressing, either nonproductive or resulting in a mucoid, tenacious or purulent sputum. Rusty or frankly bloody sputum is not encountered, but blood streaked sputum has been observed. An outstanding feature of several patients seen at the University Hospitals has been the presence of an irritating and almost constant nonproductive cough, which if untreated leaves the patient extremely uncomfortable and exhausted. Pleuritic pain occurs very infrequently. Perhaps the most outstanding features on physical examination are the minimal or absent changes in the chest when compared to the roentgenographic findings. Careful examination of the chest may elicit a diminution of the percussion note and breath sounds over the involved areas, and the presence of occasional moist râles. The roentgen film commonly reveals a patchy type of infiltration, although a lobar distribution has also been noted. The latter lesion may or may not be associated with varying degrees of atelectasis. The leukocyte count is usually within a normal range, through leukopenia has been encountered in some cases. Leukocytosis may occasionally be demonstrated after several days of illness. The clinical course and duration of the disease vary. Bradycardia has been observed frequently. The temperature may be only slightly elevated, depending upon the severity of the illness. On the other hand, an appreciable rise in temperature may mark the onset and continue for ten days to three weeks, and then gradually decline by lysis. Chills are not an uncommon occurrence. An acutely ill patient frequently exhibits cyanosis and dyspnea. The individual with a mild form

A résumé prepared at the request of the Editor.

of the disease convalesces rapidly, but a return to a normal state of well-being may be prolonged for several weeks in the more seriously ill patients. The mortality rate is extremely low, and complications are rare. The latter include sterile pleural effusions and thrombophlebitis involving the leg vessels.

Atypical pneumonia also occurs in infants and young children. Dr. John Adams and his associates[1] in the Department of Pediatrics at the University of Minnesota have described two epidemics of respiratory infections occurring in infants up to thirty-two weeks of age. The outstanding clinical features were cough, cyanosis and dyspnea. Pulmonary lesions, particularly of the upper lobes, were observed. The mortality rate for the whole group was 20 per cent, but a rate of 82 per cent occurred in the prematurely born infants. Highly suggestive evidence would indicate that the epidemics were due to a virus.

In the great majority of cases of atypical pneumonia, no etiological agent has been identified. The sulfonamides have been given to a considerable number of patients by competent investigators, and there is general agreement that the drugs do not possess any specific therapeutic value. Nevertheless, physicians confronted by acutely ill patients with evidence of pneumonia, and a febrile course that may extend two to three weeks in duration, have prescribed one of the sulfonamides. Since toxic reactions due to the sulfonamides are most likely to occur after the seventh day of chemotherapy, on many occasions the course of a patient's illness has been punctuated by drug reactions such as fever, chills, a skin eruption, and renal complications. Therefore, any one who elects to administer a sulfonamide for several days may find himself in the dilemma of not having altered the natural course of the disease, and of precipitating the patient into a more serious sequence of events because of the drug. On the other hand, pneumonia of pneumococcic origin may present an atypical clinical picture, and the patient may not yield a satisfactory specimen of sputum for diagnostic purposes, or laboratory facilities may not be readily available for a bacteriological diagnosis. It is well established that sulfonamide therapy is definitely indicated in patients with pneumococcic pneumonia. Therefore, it is the policy at the University Hospitals to give the acutely ill patient having a high fever and evidence of pulmonary infiltration the benefits of sulfonamide therapy for thirty-six to forty-eight hours. Full therapeutic doses of sulfadiazine or sulfathiazole, as advocated for the treatment of pneumococcic pneumonia, have been used. The average case of pneumococcic pneumonia will show a desired response to such therapy within this period of therapy. If the patient has not improved in this time, and diagnostic procedures such as blood cultures and sputum examinations do not reveal a bacterial origin for the illness, sulfonamide therapy is discontinued. But if prompt improvement in the patient's condition follows shortly after sulfonamide therapy has been started, treatment is extended for a few more days until a normal temperature is established. The practice of prescribing smaller prophylactic doses of a sulfonamide as long as the patient has fever has been omitted. Sulfonamide therapy is not instituted in patients having a low-grade fever, although a pulmonary lesion may be present.

With no specific treatment available, attempts should be made to keep the patient comfortable. If a moderate degree of cyanosis or dyspnea is present, oxygen therapy is indicated. The distressing cough should be controlled with opiates if necessary. Sedation with small doses of one of the barbiturates should be instituted. And finally, meticulous nursing care should be made available.

Several attempts have been made to identify the causative agent of atypical pneumonia. These efforts have been accompanied by interesting and significant results. The virus of epidemic influenza may produce pulmonary lesions, but available evidence would indicate that only a relatively few cases of atypical pneumonia up to the present have been caused by this virus. It has been known for a number of years that the virus of psittacosis may cause an atypical form of pneumonia. It has also been recognized that birds of the psittacine group such as parrakeets (love birds), parrots, cockateels, and so forth, are carriers of this virus. Recently, Meyer and his group[5] have pointed out that other species of birds may harbor the virus. It is now established that pigeons in apparent good health may carry the virus, and act as a source of human infections. Smadel[7] of the Rockefeller Institute has recently shown that ten of forty-five cases of sporadic atypical pneumonia occurring in large urban populations were caused by the virus of psitta-

cosis. Several of the patients, but not all, had been exposed either directly or indirectly to pigeons. It is of interest that the virus of lymphogranuloma venereum is closely related to the virus of psittacosis, and a few cases of atypical pneumonia have been caused by the former. Rarely, the virus of lymphocytic choriomeningitis may result in atypical pulmonary infiltrations. There is some evidence that the virus of cat pneumonitis may be the source of human cases of atypical pneumonia. Quite recently, Eaton and his group[2] in California have isolated an ill-defined infectious agent of low virulence for cotton rats from human cases of atypical pneumonia. Similar observations have just been reported by Horsfall and his associates[4] of the Rockefeller Institute.

Another interesting development is the isolation of a filter-passing rickettsia from human beings having an acute febrile illness with pneumonitis.[3] The term "American Q fever" has been given to this syndrome, because the etiological agent is identical with a species of rickettsia identified in Australia. The Australian investigators have described a human illness due to this organism and have called it Q fever.

It is becoming more and more apparent that atypical pneumonia is probably a disease due to a number of different etiological agents. It is not unlikely that the majority of cases are of virus origin. Since only a few laboratories with highly trained personnel are in a position to carry out precise diagnostic investigations as to the cause of atypical pneumonia, it is suggested that practicing physicians and institutions utilize the terminology recommended by the Surgeon General of the U. S. Army; that is, "primary atypical pneumonia, etiology unknown."[6] The term "virus pneumonia" should be reserved for those cases where a virus has been demonstrated as the causative agent.

NEUROLOGICAL COMPLICATIONS ASSOCIATED WITH SPINAL ANESTHESIA (Eight Cases)

E. M. HAMMES, M.D.
Saint Paul, Minnesota

A SYMPOSIUM on anesthesia is appropriate at this time. It is just one hundred years ago that an anesthetic was used successfully for the first time in surgery. In ancient times, Egyptian surgeons used pressure on blood vessels and nerve trunks to block sensation peripherally, and the Greeks and Romans employed opium and mandragora in wine to alleviate the suffering during operations. On March 30, 1842, Dr. Crawford Long,[31] of Jefferson, Georgia, removed a small tumor from the neck of a patient, to whom ether (three hundred and two years after its discovery and forty-seven years after it was first used medicinally) had been administered as an anesthetic. However, it was not until 1846, when Doctors Bigelow and Warren[5] demonstrated its use for surgical purposes, before a large audience at the Massachusetts General Hospital at Boston, that it gradually became employed to make modern surgery possible. In 1847, Simpson,[25] in Edinburgh, introduced the more rapidly acting chloroform. In 1879 and again in 1901 the British Medical Society[13] published a report condemning its indiscriminate use. In 1872, Ore,[13] of Lyons, injected a chloral hydrate solution intravenously, and thus was the first one to use this method for anesthetic purposes.

In 1884 Halsted[13] introduced local anesthesia by injecting cocaine intradermally. Corning[8] published his first report on spinal anesthesia in 1885, when he injected cocaine hydrochlorate in the immediate neighborhood of the spinal cord. Experimental studies and clinical observations have greatly improved this method. By refinement in technique and safer and less toxic anesthetics, spinal anesthesia has become one of the

From the Department of Neuropsychiatry, Medical School, University of Minnesota. Part of a Symposium on Anesthesia, presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1942.

methods of choice for many surgeons.[2,19,24] Some workers believe that the associated complications can be avoided in most cases. Vehrs,[28] referring to novocaine, states that none of the complications encountered are due to the novocaine or to the method, but is either inherent in the disease or due to poor technique. In a series of 3,000 cases, Foss and Shwalm[12] did not observe the slightest evidence of peripheral neuritis or sensory or motor disturbances. Lundy[22] suggests that many of the accidents following the use of spinal anesthesia in man are due to factors other than the action of the anesthetic agent, and that it seems probable that when paralysis follows the use of ordinary doses of a spinal anesthetic, the spinal cord was previously diseased. Koster and Kasman[17] were unable to demonstrate any pathologic changes in the spinal cord of autumn frogs or in human cords after spinal anesthesia. Davis and his co-workers,[10] on the other hand, believe that the various spinal anesthetics are both hemolytic and myelitic. In experimental studies on dogs, they found a varying degree of inflammatory reaction in the leptomeninges, which was constantly present; also passive changes in the ganglion cells of the gray matter of the cord, swelling and fragmentation of the axis cylinders and signs of degenerative changes in the fiber tracts of the cord, which were not pronounced after ninety days, and probably not permanent. Haven[14] found a similar inflammatory reaction of the meninges, which in the older animals reached a stage of fibrotic scarring.

Spielmeyer[27] obtained similar degenerative changes in the spinal cord itself with stovaine, and states that these reactions were due to contact effect of the drug on the myelin sheaths. Lundy[22] and his coworkers report similar degenerative reactions in dogs with procaine hydrochloride. Lindemulder[21] noted similar results with apothesine in two patients with postmortem findings, and pointed out the toxic effect of spinal anesthetics on the spinal cord and spinal nerve roots.

Behrens and Riggs[4] emphasize that marked circulatory depression by paralysis of the nerves which control vaso-constriction can be produced by spinal anesthesia. Watter[29] reports a case of hemiplegia following a spinal anesthetic of neocaine and nupercaine, and states that anoxia due to impaired circulatory efficiency was a precipitating factor. Critchley[9] reported a similar case of a few hours' duration, probably caused by a cerebral spasm or small thrombus, due in part to an associated vascular disease. Hayman and Wood[15] suggest that abducens paralysis following spinal anesthesia is not due to the toxic effect of the drug but probably due to a disturbance in dynamics of the spinal fluid.

A wide variety of neurological complications, either immediate or remote, mild or severe, may follow spinal anesthesia. Some undoubtedly are not recognized; many are not reported in the literature. In Ashworth's[1] series of 202 cases, he observed four cases with neurological sequelæ. Lindemulder, in eleven consecutive cases for prostatectomy with spinal anesthesia (apothesine), noted in three cases persistent leg pains for several months, with two deaths, twelve and twenty days postoperative. Barrie[3] reported eleven cases of meningitis, with one fatality, following spinal anesthesia. This could not be attributed to the drug but probably to contaminated water from a Berkefeld multiple filter. Critchley[9] reported eight patients with urinary retention, all in the sixth and seventh decade, except one woman, aged 40. Three of these showed clinical improvement within a few weeks; in four others, however, the symptoms persisted without aggravation up to the time of death. He believes that this syndrome is due to a noxious effect upon the cauda equina and conus medullaris, directly due to the anesthetizing substance. Ferguson[11] reported thirteen cases following durocaine or strovaine spinal anesthesia. In a thorough review of the literature, comprising over 60,000 cases of spinal anesthesia, Light[20] and his coworkers listed as sequelæ: (1) headaches; (2) sensory disturbances; (3) cranial nerve involvement, especially the 6th; (4) impaired bladder and rectal function. They also noted other more serious spinal root and cord disturbances.

Preexisting disease of the central nervous system is given as a definite contraindication to spinal anesthesia. It is a well-recognized fact that cerebral trauma of variable degree may precipitate, aggravate or accelerate the degenerative process of general paresis or cerebral arteriosclerosis.[26] Organic diseases of the spinal cord may be similarly affected.[16,30] Spinal anesthesia may likewise precipitate or aggravate a preexisting spinal cord disease that would have come on gradually at a later period, or would have progressed less rapidly if the spinal anesthetic had

not been given. The depressing effect on the circulation and the hemolytic and myelitic action of the toxic drug evidently hasten the degenerate process and increase the clinical symptoms. Many patients are still subjected to this unnecessary risk. In acute surgical emergencies, where the time element is so important, occasions may arise where it seems excusable. In cases where ample time and opportunity for careful study are available, a spinal anesthetic should not be administered. A history of a previous organic central nervous system disease or a careful neurologic examination revealing any cerebral or spinal cord disease are definite contraindications.

The following five cases are illustrative:

Case 1 (combined sclerosis of the spinal cord)—A. N., female, aged forty-eight, referred by Dr. C. C. Chatterton of Saint Paul, had suffered from pernicious anemia for five years. Her hemoglobin had varied between 45 and 92 per cent and red blood count between 2,100,000 and 4,820,000, with a typical blood smear and gastric findings, under liver therapy. She had no neurological complaints during this entire period except for occasional numb sensations in both feet. At the time of operation for a benign ovarian tumor, the hemoglobin was 82 per cent; red blood count 4,200,000. The neurological examination was negative except for moderately increased knee-jerks. No record of a sensory examination was noted on the hospital sheet. The operation was uneventful and was performed under spinocaine spinal anesthesia at the third lumbar interspace. She stated that at the time of the injection it felt as if the needle was piercing some nerves; sharp shooting pains radiated down the legs and the legs felt as if they were drawing up. The surgical convalescence progressed satisfactorily. On the third postoperative day, she developed a dull aching pain in both legs and some numb sensations in her hands. This continued and eleven days later, when she attempted to get up, she was unable to walk without assistance because of lack of balance and because she "could not tell where she put her feet." She has been unable to walk without assistance since that time. She also developed some bladder disturbances. I first saw her one year after her operation and she presented a typical picture of a combined sclerosis of the spinal cord. The cranial nerves were normal. Both upper extremities were normal except for an ataxia with the finger to nose test, and impaired tactile, pain and vibratory sense on the palmar and dorsal surface of both hands. The Romberg was 4 plus. Her gait was ataxic and she could walk only with assistance. Both knee and ankle jerks were 3 plus, a bilaterally positive Babinski and ankle-clonus were present. Tactile and pain sense were diminished from the level of the umbilicus down, including both lower extremities, where position and vibration sense were also lost.

Her hemoglobin was 84 per cent; red blood count 4,500,000; leukocytes 7200; gastric analysis normal except for the absence of free hydrochloric acid. Her blood Wassermann was negative; spinal fluid clear, pressure 170 mm. water, no bloc, globulin a trace, cells 17 lymphocytes, Wassermann and colloidal gold negative, quantitative protein 38 mg. per 100 c.c. basal metabolism —15, blood pressure 140 systolic, 80 diastolic. There was no further improvement under liver therapy. Legal action was instituted by the patient and a settlement was made out of court.

In this case the clinical neurologic syndrome and presumably the degenerative changes in the spinal cord progressed more rapidly than is usually encountered in combined sclerosis associated with pernicious anemia. It would seem that the toxic effect of or the circulatory changes produced by the spinal anesthetic were at least in part responsible for this fairly acute development. All cases of pernicious anemia should be considered as potential combined sclerosis of the spinal cord when determining what anesthesia to use. This case well illustrates the danger of medico-legal complications in organic neurological disease, where a spinal anesthesia is employed.

Case 2 (multiple sclerosis).—C. L., female, aged twenty-nine, had her first attack of diplopia on September 20, 1937, of one month's duration, with recovery. She remained well until August 16, 1938. On awakening that morning she noticed marked "prickly sensations" in both feet, which extended to the knees within three days, and her gait became somewhat awkward. Examination on August 21, 1938, was negative throughout except for absent left abdominal reflexes, moderate hypertonicity of both lower extremities, a left positive Babinski, and indefinite sensory impairment over both feet. All laboratory findings were normal except the spinal fluid. The spinal fluid was clear, pressure 160 mm. water, no bloc, 12 cells, negative Wassermann, colloidal gold curve 3332100000, quantitative protein 70 mg. per 100 c.c. A diagnosis of multiple sclerosis was made. Her symptoms subsided after five weeks, except for a positive left Babinski. She remained well until March, 1939, when she had a recurrence of her previous symptoms with diplopia, numbness of her left hand and vertigo. She again recovered clinically, and during her entire illness was able to continue with her work as a stenographer. She remained well until January 12, 1942 (almost three years), when she had an attack of acute appendicitis. An appendectomy was performed under spinal anesthesia. Novocaine crystals 130 mg. in 2 c.c. spinal fluid were injected in the third lumbar interspace. Because of the urgent need for immediate operation, the surgeon had not obtained her previous neurological history. The operation and surgical convalescence were uneventful. On the fourth postoperative day she complained of diplopia, weakness and numbness of both lower extremities and difficulty in voiding.

Examination on the sixth postoperative day revealed that the patient was somewhat depressed and emotional. All cranial nerves were normal except for a paresis of the left abducens. The upper extremities were negative except for a bilateral intention tremor. All abdominal reflexes were absent. The right lower extremity was hypotonic, muscle strength greatly reduced, knee and ankle-jerks diminished, no clonus, normal plantar response. The left lower extremity was spastic and ataxic, knee and ankle jerks increased, Babinski positive. Sensation was normal over the face, trunk and both upper extremities. Over the entire right leg, from Poupart's ligament down, tactile, pain and temperature senses were markedly impaired. The outer surface of the left thigh was similarly involved. She also had urinary incontinence. The spinal fluid was clear, pressure 165 mm. water, no bloc, 4 cells, Wassermann negative, colloidal gold curve 2344310000, quantitative protein 52 mg. per 100 c.c. Her condition has remained the same, with very little change in the clinical picture.

Two similar cases of multiple sclerosis, in which the symptoms appeared to progress rather rapidly following a spinal anesthesia were observed at the Mayo Clinic.[23] Critchley[9] reported a case of a male, aged twenty-eight years, who for several years had attacks of vertigo. These improved to such a degree that he was able to join the regular Army. He was operated upon for a derangement of the knee joint, under spinal anesthesia. On the third postoperative day he developed a retrobulbar neuritis, and some time later a typical multiple sclerosis. It is difficult to evaluate the causative relationship in these cases.

Although multiple sclerosis has its remissions and exacerbations without any definite cause, it seems significant that the progress of the disease in each instance was unusually rapid and marked following spinal anesthesia.

Case 3 (tabes).—F. B., male, aged thirty-seven, was referred by Dr. H. B. Zimmerman, Saint Paul. His family and personal history were negative and he had no previous preoperative neurological manifestations. He was admitted to the Miller Hospital on April 27, 1938, with an acute abdomen. Within a few hours a gangrenous appendix was removed under spinal anesthesia, 150 mg. novocaine in 3 c.c. of spinal fluid at the third lumbar interspace being used. The postoperative and surgical convalescence were uneventful. On May 2, the fifth postoperative day, the patient complained of numbness and severe shooting pains in both lower extremities, with some impairment of bladder control. Neurological examination at this time revealed pupils equal and round, very sluggish to light, absent knee and ankle jerks, no clonus, normal plantar response, muscle strength normal, no nerve trunk tenderness, ataxia with the knee heel test. In both lower extremities, tactile, pain and position senses were impaired. After he was able to get up, the Romberg was positive and his gait was ataxic. Hemoglobin was 82 per cent, red blood count 4,620,000, leukocytes 8,400; urine normal; blood pressure 120 systolic, —70 diastolic; blood Wassermann 4 plus. The spinal fluid was clear, pressure normal, 12 cells (lymphocytes), globulin trace, Wassermann 4 plus, colloidal gold curve 2343210000. Under antileutic treatment, he made satisfactory improvement, so that after four months he was able to return to his occupation as a clerk. He continued treatment and the tabes has become stationary.

Case 4 (general paresis).—C. M., male, aged fifty-nine years, was admitted to the surgical service at the Ancker Hospital, Saint Paul, on January 19, 1942. His personal history was negative except for marked alcoholism, until 1939, and a right inguinal hernia of six years' duration. The neurological examination was negative except that both pupils were irregular in outline. The light reflex in the right pupil was normal; in the left there was only a slight response. The mental examination revealed no abnormalities and he appeared normal during his two preoperative days at the hospital. On January 21, 1942, at 9:45 a.m. a right inguinal herniorrphy was done, under spinal anesthesia. Novocaine crystals, 150 mg. in 2 c.c. of spinal fluid, were injected at the level of the third lumbar interspace. The operation was uneventful and the patient was returned to the ward in good condition. He was normal mentally until about 6 p.m., eight hours postoperative. He then became irrational, noisy, disoriented and extremely restless. He refused to stay in bed. The following day restraints were necessary; he refused to eat, became abusive and profane. He appeared terrified because he thought someone was trying to kill him. His phychosis continued. On January 28, 1942, he was examined by Dr. George Ruhberg, of the Neuropsychiatric Department, and a diagnosis of probable general paresis was made. Examination on February 1, 1942, was negative except for irregular and sluggish pupils and moderately increased knee jerks. He was noisy, profane and rambling in his conversation, would not answer questions, had involuntary urine and stool. He was given two intravenous injections of 3 gm. tryparsamide. On February 9, 1942, he developed a bronchopneumonia, with a temperature of 104 for six days, then gradually recovered from the pneumonia. There was no improvement in the psychosis after the tryparsamide injections or after the period of hyperpyrexia. He developed an exfoliative dermatitis, which gradually subsided. He had been given tryparsamide, sulfathiazole and sodium luminal in large doses. His psychosis progressed and within six weeks he presented a dementing type of general paresis. On March 6, 1942, he was committed to the State Hospital for the Insane. On January 20, 1942 his hemoglobin was 74 per cent; red blood count 4,040,000; leukocytes 8,100; urine normal; blood pressure 130 systolic, 60 diastolic. On January 23, 1942, his blood Wassermann was 4 plus. On February 4, 1942, the spinal fluid was clear, contained a trace of globulin, 10

ells, all lymphocytes, quantitative protein 76 mg. per 00 c.c., Wassermann 4 plus, colloidal gold curve 555543-100.

These two cases of syphilis of the central nervous system, both precipitated following spinal nesthesia, emphasize the importance of careful neurological examination. Suggestive signs, such s sluggish pupils, warrant delay until laboratory tudies have been completed before determining he anesthetic to be selected.

We have observed several patients with tabes nd one with cerebral vascular syphilis, who did ot show any increase in the neurological syndrome following spinal anesthesia for abdominal urgery. Clinical experience would suggest that ome other type of anesthesia would be accompanied with less risk.

Another interesting organic neurological patient, who was examined last winter, developed further neurological complications following pinal anesthesia. This man, aged seventy, had n apoplectic attack, with a left hemiplegia, eighteen months previously. After a prostatectomy nder metacaine spinal anesthesia, he developed a severe radiculitis with a flaccid paraplegia.

The following three cases did not manifest any preoperative neurological symptoms or signs.

Case 5 (chronic adhesive arachnoiditis, with probable ascending myelitis).—M. J., female, aged twenty-one, was referred by Dr. R. F. Mears, Northfield, Minnesota, on February 10, 1942. Her personal history revealed that since May, 1941, she had had repeated attacks of right lower abdominal pain, accompanied by a low grade temperature and a leukocytosis around 9500. On October 15, 1941, she was given a spinal injection of 0.5 c.c. of 20 per cent metacaine diluted in 3.5 c.c. spinal fluid in the third lumbar interspace. The spinal fluid was normal in color. Within ten minutes her respiration ceased. Artificial respiration was resorted to and an intravenous injection of 3 c.c. of metrazzol was administered. After forty-five minutes she appeared normal. She complained of numbness and weakness of the left leg and some difficulty in starting the flow of urine. This gradually improved.

On October 20, under nitrous oxide and ether anesthesia, a subacute appendix and a large cystic and degenerated ovary were removed. The surgical progress was uneventful. Numbness and weakness of the left leg continued for several weeks, with absent knee and ankle jerk. This gradually improved. By the middle of December, she was able to walk quite normally except for a slight limp of her left leg and some numbness of the left foot. Marked constipation was present. During the last week in December, she developed considerable low back pain and her left leg gradually became weaker. Dr. Mears reported that examination on January 8, 1942, revealed that the left leg was hypotonic, the knee and ankle jerks absent, and there was impaired tactile, pain and temperature sense of the entire leg. In the right leg, knee and ankle jerk were moderately increased, sensation normal.

On January 30, she sustained a third degree burn over her sacral region, without any pain or discomfort. The weakness in her left leg gradually became more pronounced and she again developed difficulty in starting her urine. At about this time, involuntary contractions of the muscles of her left leg were observed. She stated that her right leg felt and functioned normally. Examination on February 10, 1942, revealed a well-nourished female, pulse 100, temperature normal. All cranial nerves were normal; upper extremities were negative except for a fine tremor, some cyanosis and hyperhidrosis of both hands. The upper abdominal reflexes were normal; lower were absent. The Romberg test was positive. She walked with a marked limp. The right leg was somewhat spastic, knee and ankle jerks increased, Babinski positive, no clonus. The left leg was hypotonic, muscle strength somewhat decreased, definite ataxia, absent knee and ankle jerks, no plantal response, no nerve trunk tenderness or vasomotor or trophic changes. Occasional involuntary muscular contractions occurred. Sensation was normal over the face, both upper extremities and the trunk to a level of the eleventh dorsal segment. Over the remainder of the trunk, tactile, pain and temperature sense were impaired. Over the entire right leg, tactile, pain and temperature sense were impaired; position and vibration sense were normal. Over the entire left leg all forms of sensation were lost. There was a third degree sloughing burn over the sacrum.

Her urine was normal except for a few pus cells, hemoglobin 84 per cent; red blood count 4,700,000; leukocytes 8,200; blood pressure 120 systolic; 70 diastolic; blood Wassermann negative. On February 11, 1942, a spinal puncture in the recumbent posture was attemped, but no fluid obtained. In the sitting posture, the spinal fluid was under decreased pressure, with a definite bloc. Eight drops were obtained in two minutes. The fluid was clear, slightly yellowish; the Wassermann was negative. She was discharged from the hospital on February 21, 1942, and readmitted on March 16, 1942. During the interval, her symptoms had increased, she was unable to walk, had great difficulty in voiding, the involuntary contractions in both legs had become so pronounced that occasionally her left knee would strike the abdomen. The right leg had become very spastic, with a definite patellar and ankleclonus, and her sensory level at this time had risen to the eighth dorsal segment. The sloughing area over the sacrum was healing satisfactorily. Five drops of clear, xanthochromic spinal fluid were obtained by spinal puncture, in the sitting posture. This coagulated spontaneously.

On March 24, 1942, Dr. H. O. Peterson, roentgenologist, injected 4 c.c. of lipiodol in the third lumbar interspace, and reported the characteristic changes described in arachnoiditis (Fig. 1). An attempt was made

to remove the lipiodol by the Kubik and Hampton[29] method but only 2 c.c. were obtained. The remainder was infiltrated between the adhesions and could not be removed. The patient was discharged from the hospital on March 26, 1942, without any change in the

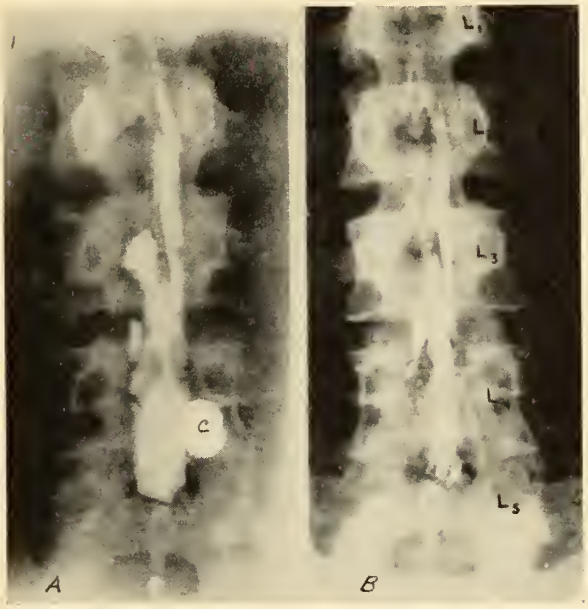

Fig. 1. Lipiodol Myelography: 4 c.c. injected at third lumbar interspace.
A. The outline of the canal at the level of the fifth lumbar vertebra is slightly irregular but there is no obstruction. There is complete obstruction to the flow of the lipiodol at the level of the second lumbar vertebra. The obstructed end is very irregular with the obstruction being most marked on the right side, where it begins at the level of the third lumbar vertebra. The appearance is fairly characteristic of the changes described in arachnoiditis with marked adhesions and obliteration of the subarachnoid space. *B.* Myelogram after removal of 2 c.c. lipiodol (Kubich-Hampton method). The remainder was infiltrated between the adhesions and could not be removed. *C.* Spinal puncture needle.

clinical syndrome, and without any apparent reaction from the lipiodol injection. On May 15, 1942, she was operated on by Dr. G. S. Baker, Mayo Clinic, who kindly submitted the following report:

"There was complete anesthesia for all forms of stimuli below the 8th thoracic segment and we were unable to obtain any cerebrospinal fluid, as the lumbar spinal canal was entirely dry. The spines and laminæ of the 7th, 8th and 9th thoracic vertebræ were removed and when the dura was opened we found that it was quite adherent to the arachnoid, and the cord itself, for the entire distance which we explored. Adhesions had formed all about the cord tissue. A small specimen of the arachnoid was removed for pathologic diagnosis and the tissue showed chronic fibrous arachnoiditis, with evidence of old blood pigment in the tissue."

Dr. Baker suggested that it is quite possible that the patient had an intraspinal hemorrhage which could account for the entire syndrome. At the time of her discharge there was no change from the preoperative findings.

A report received from Dr. Mears, July 1, 1942, stated that her condition has remained stationary.

Another case of chronic arachnoiditis was observed a few months ago in a patient seventy-one years old. He had a prostatectomy under metacaine spinal anesthesia, and developed a similar clinical picture and spinal fluid findings as the above case. However, his symptoms developed quite rapidly for forty-eight hours postoperative, after which time they became stationary.

In all probability in these two cases, inflammatory and fibrotic changes developed in the meninges of the spinal cord, due to the anesthetic, as has been demonstrated by Davis[10] and Haven.[14] An extension of this process with subsequent involvement of the spinal circulation readily explains the clinical syndrome, manifested as a slowly ascending myelitis.

Brain and Russell[6] reported a somewhat similar case following spinocaine anesthesia. The spinal fluid was normal eight weeks postoperative. He died sixteen weeks later and pathologic examination revealed a massive softening of the spinal cord, up to the twelfth thoracic segment, with inflammatory reaction in the pia, and perivascular changes. In Brock's[7] case, the patient presented a cauda equina neuritis following spinal anesthesia. During the next twenty-nine months a transverse myelitis and radiculitis developed which ultimately proved fatal. The clinical course was characterized by long periods during which the condition was stationary. With subsequent exacerbations, higher levels of the cord became involved. He suggests that the original chemotoxic effect on the spinal cord, by the anesthetic, may have devitalized the neural tissue so that other factors, such as a dormant virus, may become active and cause further involvement.

Case 6 (Toxic psychosis).—M. F., male, aged sixty one, was referred by Dr. C. J. Glaspel of Grafton, North Dakota, on May 9, 1942. On March 28 1942, the patient developed recurrent attacks of lower right abdominal pain. He consulted his physician during the night of March 31, 1942, and was operated upon the following morning. A ruptured gangrenous appendix was removed and a generalized peritonitis was found. The operation was performed under spinal anesthesia, 2 c.c. of spinocaine in 2 c.c. of spinal fluid in the second lumbar interspace. The patient ran a septic temperature around 102 degrees F. for two weeks with marked abdominal distention. During the first week postoperatively his blood pressure was 180 systolic, —100 diastolic, and since them has been 140 systolic, —90 diastolic. Following his operation he slept for six hours, probably due to a hypodermic of morphine. On awakening he was extremely restless and insisted on getting out of bed. The following day he was confused, disorientated and refused to take liquids

He developed a marked insomnia which was not relieved by sedatives. He appeared quite toxic and developed hallucinations of sight and hearing. He had loss of bladder and rectal control. He gradually developed short periods during which he was less disturbed. He lost about thirty pounds in weight.

Our neurological examination on May 9, 1942, was normal. He was extremely restless, somewhat dehydrated, had hallucinations of sight, would not answer questions, and had involuntary urine and stool. He had to be kept in restraint, and tube feeding was necessary. His temperature was normal; pulse 100. Hemoglobin was 90 per cent; red blood count 4,940,000; leukocytes 13,700; urine normal; blood Wassermann negative. The spinal fluid was clear, pressure 180 m.m. water, no bloc, one cell, Wassermann and colloidal gold curve negative, quantitative protein 45 mg. per 100 c.c. He improved physically, gained in weight, and became somewhat clearer mentally. He continued to have involuntaries and refused to eat. About June 1, 1942, he developed four carbuncles, located around the gluteal region, with some temperature and a leukocytosis of 21,500. The carbuncles continued over a period of one month, with new ones appearing. His mental status gradually changed, his hallucinations subsided and he developed a characteristic Korsakoff's psychosis.* This case presents a typical syndrome of a toxic psychosis secondary to the acute abdominal infection. This would have developed regardless of the type of anesthesia employed.

Summary

Eight cases of neurological complications associated with spinal anesthesia are reported, six of which are described in detail.

Five cases of preoperative organic neurological disorders were aggravated following spinal anesthesia. A complete personal history and a thorough preoperative neurological examination will assist in eliminating this unnecessary risk.

Although no definite conclusions can be drawn as to the causative relationship, these cases definitely demonstrate that the chemotoxic effect of the various spinal anesthetics aggravate preëxisting neurological diseases.

Serious complications in individuals neurologically normal are relatively infrequent and in properly selected cases spinal anesthesia still holds an important place in the surgeon's armamentarium.

*He was discharged from the hospital on August 14, 1942, and returned home. On September 20, 1942, Dr. Glaspell reported that he was slowly improving, but still confused and disinterested.

TUBERCULOSIS IN WAR TIMES

Fire is fire, no matter what the fuel, but when gasoline is thrown on a flame a dangerous explosion results. Tuberculosis is the same disease now as in peacetime, but war invariably favors a flare-up of tuberculosis and creates new difficulties for those who must combat the blaze. The hard-pressed general practitioner is a seasoned fire-fighter whose aid must be enlisted and whose effort must be supported if smoldering tuberculosis, lately coming under control, is to be prevented from spreading into a serious conflagration. Even veteran firemen, however, periodically examine their equipment and drill themselves to increase their efficiency.

SPINAL ANESTHESIA—IMPORTANT PRINCIPLES

RALPH T. KNIGHT, B.A., M.D., F.A.C.S.

Associate Professor and Director of the Division of Anesthesia
University of Minnesota
Minneapolis, Minnesota

SPINAL anesthesia is one of the most helpful and most successful procedures which has ever been devised in medicine. From its early beginnings with the daring use of one of medicine's most toxic drugs, cocaine, it has been painstakingly developed until now a number of much less toxic drugs are available, which possess such a variation in characteristics as to make possible a very helpful choice for each individual case. Methods and techniques, too, have been improved so that with the proper application of them excellent anesthetic results can be obtained, as needed in each instance, and untoward consequences can be almost certainly avoided. I think one can definitely state that spinal anesthesia is a helpful and not a dangerous procedure, in which, however, one may easily do harm if he neglects or does not understand, certain well-recognized and necessary precautions. The writer believes this statement so completely that three years ago, when confronted with the necessity of having surgery and an anesthetic for himself, he quickly and unhesitatingly chose spinal anesthesia to be administered by an anesthetist who he was sure knew, considered and practiced all of the important details of choice and technique. Metycaine was used because both my anesthetist and myself had had much favorable and no unfavorable experience with it, and because I had been found to be sensitive to procaine. I say this because metycaine has been criticized.

Several of these details need especial emphasis at this time:

1. *The spinal puncture.* Trauma to nerve roots and spinal cord can be best avoided by making a perfect mid-line puncture, "in the middle of the center," as Dr. Lundy is wont to say. To accomplish this the patient must be exactly placed with hips and shoulders exactly perpendicular and the spinal column arched and straightly horizontal. Too often this simplest of principles is imperfectly followed. The needle, after being tested, should then be handled without bending and inserted horizontally, and as slowly as it is possible to make anything move, until its point passes through the resistance of the ligamentum flavum and then of the dura. Needless to say, if the resistance of bone is encountered one must never push but must withdraw the needle to the subcutaneous tissues, re-survey the landmarks and again insert it in a corrected direction. If when thus slowly introduced the needle should touch periosteum or nerve tissue a warning is received before any damage is done. If, however, it is introduced too roughly or too fast it may plunge into periosteum, nerve root, or cord and cause definite trauma.

In the matter of producing successful spinal anesthesia, unless the needle bevel has been introduced completely into the free subarachnoid space so that fluid may be aspirated freely, rapidly, and without hindrance, there is only a remote chance that the injection of the anesthetic solution will bring about the desired anesthesia. There is, however, in such case a definite chance that if injected the solution will be insufficiently diluted with spinal fluid and will cause prolonged or permanent damage to the nerve tissue.

2. *The concentration of the solution injected.* When the needle has been successfully introduced the spinal anesthetic procedure has only just begun. The recognized strengths of the solutions of the various drugs, as they exist in the syringe before injection, and above which one cannot raise them without danger, are as follows: procaine, 5 per cent; metycaine, 5 per cent; pontocaine, 0.5 per cent (1-200); nupercaine, 1-1500. I do not believe one is justified in ever increasing these strengths in the hope of prolonging the working duration of the anesthesia. Each of the drugs is longer in action in the order named and if one is especially anxious for longer duration the continuous or fractional technique is available. I believe there is no doubt that too highly concentrated solutions have caused vastly more cases of nerve damage than has trauma by the needle.

Part of a Symposium on Anesthesia presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1942.

3. *The rate of injection.* This third precaution is a corollary of the second. Many who use spinal anesthesia have felt that they were using caution by injecting the solution very slowly. The reverse is true. When injected slowly the solution remains discrete from the spinal fluid and, if distinctly heavier than spinal fluid as in the case of procaine and metycaine, it rolls rapidly downhill when the patient's head is shifted downward or the Trendelenburg position is assumed within quite some time after the injection. Further, and this is the point we are especially emphasizing in this paragraph, the concentrations mentioned above are themselves definitely high enough to do damage. They can only be used because they are to be diluted immediately with spinal fluid. If, then, by injecting slowly, one avoids this immediate dilution, he invites trouble. My attention has been called to at least one case in which I feel sure this was true. Lundy has for years advocated the injection at the rate of 0.5 c.c. per second, and this method has proven very satisfactory in the hands of all who have used it. Undoubtedly a considerably faster rate can be used with safety.

4. *Control of the height of anesthesia produced.* This is managed by varying the site o finjection, the amount of solution injected, the specific gravity of the solution and the position of the patient after injection. An average dose of procaine or metycaine in 5 per cent solution injected at the rate of 0.5 c.c. per second, if the patient is kept level, will create anesthesia about five segments above the site of injection. If the head of the table is at once lowered slightly the spread will be increased. Pontocaine in 0.5 per cent solution injected in the same way will not spread so far because it is almost exactly the same specific gravity as spinal fluid and the intermixture is therefore less encouraged. Increase of the amount of solution increases the height of anesthesia. Nupercaine, 1-1500, is much lighter than spinal fluid and tends to rise in it. If the patient's head is raised too suddenly or too high or remains up too long, immediately after injection, anesthesia may rise too high and interfere with respiration. On the other hand, the upward position of the head under close observation and management by one with experience may be safely used to control the height of anesthesia to be obtained by the use of nupercaine. Likewise by using the heavier solutions such as procaine or metycaine, or by making pontocaine or nupercaine heavy with added dextrose, one may raise the head and neck on a pillow, lower the shoulders considerably below the pelvis, and thus conveniently produce anesthesia to the fifth thoracic segment. If these maneuvers are not well managed, as they should be, and if, for instance, the Trendelenburg position is invoked too soon or without proper flexion of the head and neck, anesthesia may advance beyond control and cause respiratory arrest by paralyzing all of the intercostals and the diaphragm. Although this attack has advanced well beyond the first lines of defense it need not at all be a tragedy. No stimulants are needed or even beneficial if by some artificial means one keeps air or oxygen exchanging in and out of the lungs until anesthesia recedes and the patient can resume automatic breathing. I doubt whether one is ever justified in doing a spinal anesthesia unless he is equipped with a machine which provides oxygen, a close-fitting mask, and a rebreathing bag with which one can perform artificial respiration, or its equivalent such as a resuscitating machine. If one really knows spinal anesthesia he may go through a lifetime without causing respiratory arrest, but through some little failure on the part of himself or an assistant it might occur. There can be no justification for doing a major procedure of this kind without proper equipment. An emergency necessitating it would be hard to conjure up. Such a death could be due to nothing but neglect.

5. *The control of the blood pressure.* Considerable fall in blood pressure is dangerous, especially in the middle-aged or older group and in those with decompensated hearts, because of the accompanying medullary, cerebral and cardiac hypoxia and tendency to thrombosis. It is combatted by the administration of oxygen, which as stated above, should always be at hand, and which should be liberally used in many cases routinely, and by lowering the head as soon and as much as consistent with the anesthetic injected. The most important control, however, is in the use of the pressor drugs.

In good risk patients a prophylactic dose of 25 to 50 mgm. of ephedrine injected intramuscularly before injecting the spinal anesthetic is usually sufficient to maintain the blood pressure at or near its usual level. If, however, the anesthesia is rather high, a fall of pressure may oc-

cur and must be met by further doses of ephedrine, if necessary, in small units of 10 to 15 mgms. intravenously.

In poorer risks and older people, one must exercise special care to keep the blood pressure at or near its preanesthetic level. If the latter is high, one must not inject a prophylactic dose of ephedrine until he knows that the spinal needle is within the dura and that spinal fluid can be freely aspirated so that he is definitely ready to inject the anesthetic. He then should inject intramuscularly a dose of the pressor drug which he believes will be sufficient to prevent a significant bood pressure fall, and should wait five minutes before completing his spinal anesthetic procedure. Old people with high blood pressures are the very ones who are apt to have spinal arthritis which may delay or even prevent a correct spinal tap. The writer has known of three deaths due to the too optimistic injection of ephedrine before attempting the spinal puncture, or to the injection of too large an amount. The result was a severe and prolonged rise of blood pressure followed by cerebral accident. The prophylactic dose of the pressor drug should therefore be conservative, about 25 mgms. of ephedrine. One should then be prepared to inject a small amount intravenously if the pressure starts to decline. Ten mgms. is enough until one waits with the needle in the vein for one minute or more to see what effect will take place. Additional amounts in units of 5 mgms. can then be added as indicated until the blood pressure has become stabilized.

A most effective combination, and a favorite one with the writer, is a mixture of one mgm. of neosynephrin to 20 mgm. of ephedrine. This is especially helpful for old people to whom one must be careful not to give too much too soon, but must certainly avoid too little and too late. The above amount is a good average initial intramuscular dose. Each intravenous unit should not be more than one-fourth or one-fifth that much. Neosynephrin alone, in doses frequently spoken of, 5 mgms., for example, is dynamite and frequently sends the blood pressure skyrocketing one hundred and fifty points.

The above five points of special precaution are concerned with the dangers attendant upon the administration of spinal anesthesia. This paper must leave unconsidered the details of dosage and technique with the various drugs for producing anesthesia for various surgical procedures.

Neither is sufficient time available to discuss those patients for whom spinal anesthesia should be definitely avoided or seriously questioned. Possibly their number is growing somewhat less as our familiarity with all types and modifications of spinal anesthesia increases. Certainly no patient with a lesion of the spinal cord or with primary anemia should be given spinal anesthesia. One suffering from secondary anemia, hemorrhage, or shock should certainly have those conditions first brought under control. One with cardiac decompensation should not be given spinal anesthesia until all other forms of anesthesia have been carefuly considered and compared in risk in every way and evaluated as carrying at least no less risk than a spinal.

If used with due attention to all the known and recognized factors of safety and proficiency, spinal anesthesia should continue to occupy a high place among the standard and most helpful procedures in medicine.

SMALLPOX VACCINATIONS GIVEN TO 36,000 IN DISTRICT OF COLUMBIA

About 36,000 residents of Washington, D. C., most of them employes of the federal government, have been vaccinated against smallpox since last December, the District of Columbia Health Department announced. About 10,000 of these vaccinations were given by physicians of the health department and the rest by the medical staffs of various federal and District agencies.

The outbreak of smallpox in nearby Pennsylvania stimulated the current vaccination drive, but Dr. George C. Ruhland, health officer of the District of Columbia, is still urging that all persons living there who have never been vaccinated should take this health protection immediately.

The reason is that Washington is the crossroads of the world in war activities. People are coming not only from the entire nation but from all over the world, many of them from regions where vaccination against smallpox is not practiced, and this increases the danger to unvaccinated persons there.

No case of smallpox has been reported in Washington in the past ten years.—*Science News Letter,* March 13, 1943.

NEWER TRENDS IN INTRAVENOUS ANESTHESIA

JOHN S. LUNDY, M.D.
and
EDWARD B. TUOHY, M.D., M.S. (Anes.)
Rochester, Minnesota

The intravenous method of producing general anesthesia has a great appeal to the experienced anesthetist as well as to the surgeon, patient and others. It is increasing in favor because patients who have been anesthetized once in this fashion usually request it when, and if, they must be anesthetized subsequently.

The original technique of giving large doses of the anesthetic agent and withdrawing the needle has been abandoned in favor of intermittent injections of doses that are safe but sufficient. The principle of this technique of injection is not fundamentally different from that of the administration of ether by the open drop method. With both procedures the anesthetic agent is given if, and when, and in whatever quantity it is needed.

The use of a 5 or 10 per cent solution of the anesthetic agent has been abandoned and at present a 2.5 per cent solution is used so that the untoward results from extravenous injections are no longer seen.

Various devices have been designed so that one person simultaneously may administer the intravenous anesthetic agent, maintain an adequate airway for the patient and, if necessary, administer a gaseous anesthetic agent by inhalation.

Use of intravenous anesthesia as a part of balanced anesthesia has been the latest trend in the use of the method. Preliminary medication is essential to the optimal application of intravenous anesthesia. The usual preoperative medication for the average adult is 1½ grains (0.1 gm.) of pentobarbital sodium (Nembutal) by mouth at bedtime the night before the operation; this dose is repeated the first thing in the morning, when the patient awakens, or at 7 a.m. In addition, 1/6 grain (0.01 gm.) of morphine sulfate and 1/150 grain (0.00043 gm.) of atrophine sulfate are given about forty minutes before operation. Local, regional or spinal anesthesia is employed together with intravenous anesthesia with pentothal sodium at the same time that a mixture of 50 per cent nitrous oxide and 50 per cent oxygen is administered by inhalation. This form of balanced anesthesia has certain demonstrable advantages. The preliminary medication brings the patient to the operating room in a placid condition. The administration of a local anesthetic agent can be carried out either before or after the induction of anesthesia by the intravenous administration of pentothal sodium. The convulsant effect of an overdose of the local anesthetic agent is largely counteracted by the preoperative administration of a barbiturate and the intravenous administration of pentothal sodium. Pain of injection of the local anesthetic agent is neutralized by the analgesic effect of morphine plus the anesthetic effect of pentothal sodium. The preoperative administration of atropine results, among other things, in drying secretions and little or no accumulation of foreign material in the oropharynx. It also tends to prevent laryngospasm which may develop readily because pentothal sodium is a thiobarbiturate and seems to increase the activity of the throat reflexes. In cases in which intravenous anesthesia is to be used for manipulation within the throat, a local surface anesthetic agent, such as cocaine, must be applied just as should be done if the manipulation, bronchoscopy for example, were to be done with the patient under local anesthesia only. Because in deep surgical anesthesia with pentothal sodium respiration is depressed markedly, at first it was found necessary to give oxygen also. Later it was found that a combination of 50 per cent nitrous oxide and 50 per cent oxygen was just as effective in supplying the patient with oxygen and definitely decreased the amount of pentothal sodium that was necessary.

A point of special value to remember when pentothal sodium is to be administered with a spinal anesthetic agent is that the spinal anesthetic agent produces intercostal paralysis, the pentothal sodium central paralysis and the result is extraordinarily quiet respiration. The adminis-

From the Section on Anesthesia, The Mayo Clinic, Rochester, Minnesota. Part of a Symposium on Anesthesia presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30, 1942. This paper was prepared before May 25, 1942, when Dr. E. B. Tuohy entered the service.

tration of a combination of oxygen and nitrous oxide, half and half, reduces the dose of pentothal sodium enough so that respiration remains adequate. When this combination of pentothal sodium given intravenously and a mixture of half nitrous oxide and half oxygen by inhalation is used, it is important that these general anesthetic agents are not administered for at least fifteen or twenty minutes after the spinal anesthetic agent has been administered and that determinations of blood pressure are made at frequent intervals while this type of anesthesia is maintained.

Because of the relative suddenness with which an untoward result may develop, pentothal sodium is seldom used for the preoperative prediction of the probable result of sympathectomy on hypertensive patients. The use of divided doses of sodium amytal by mouth can give practically the same information although the test requires a longer period of time with sodium amytal than with pentothal sodium. However, pentothal sodium given intravenously in small doses (7 to 10 c.c. of a 2.5 per cent solution) before inhalation anesthetic agents are administered has proved advantageous for hypertensive patients. There is little change, however, in the contraindications to the use of pentothal sodium: it should not be used for children less than ten years of age unless they are large and 50 per cent oxygen and 50 per cent nitrous oxide is administered simultaneously, for patients who have cardiac disease and decompensation, nor for patients in marked shock especially when it is due to marked loss of blood.

The use of pentothal sodium in doses sufficient only to produce light surgical anesthesia for such operations as extraction of teeth has been described by Hubbell and in time may be used widely.

Barbiturates given intravenously have not produced satisfactory anesthesia for normal deliveries but have been satisfactory for cesarean section when given in association with local anesthetic agents. The most satisfactory procedure has been about as follows: The line of incision is infiltrated with a local anesthetic agent and incision is made through the abdominal wall. The intravenous anesthetic agent is administered just before the incision is made through the uterine wall. The result is general anesthesia for the mother and no anesthesia for the child. The child's breathing is spontaneous as soon as the head is delivered from the uterus.

The art of venipuncture is being mastered by those who would use pentothal sodium to induce anesthesia since it is not possible to use this agent for anesthesia if venipuncture cannot be performed. The application of heat to the extremities before venipuncture expedites the procedure.

The use of pentothal sodium instead of ether as an auxillary agent to reinforce anesthesia with nitrous oxide and oxygen permits a technique which is fireproof and has been of decided advantage in many procedures when a fireproof method was necessary and general anesthesia was desired.

The intravenous method of anesthesia is still in the early stage of development. We expect the method to be used more and more widely, especially if better agents can be obtained or if investigation of older agents reveals applicability to this method.

AEROPHAGIA

G. HOYME, M.D.
Eau Claire, Wisconsin

MUCH has been written concering aerophagia and its treatment by authorities too numerous to mention. My interest in the subject was kindled after several months of postgraduate study in the clinic of B. W. Sippy, and my purpose today is to present in brief an epitome of only the bare requisite essentials.

Eighty per cent of my patients with gastro-intestinal disturbances have symptoms of abdominal fullness, gas and belching. These may be brought on or intensified by aerophagia, which is a self-induced method for the so-called removal of "gas." The treatment of this condition has varied from placing a cork between the teeth to the latest suggestion whereby the patient is taught "to swallow properly by closing the lips, sucking in

Presented before the Minnesota Society of Internal Medicine, Duluth, Minnesota, May 23, 1942, and the American Therapeutic Society, Atlantic City, New Jersey, June, 1942.

the cheeks and pressing the tongue against the roof of the mouth before swallowing, whether he is taking food, liquids, or merely saliva. The patient is also instructed to make a water seal with his upper lip on the glass when drinking liquids in order to prevent the intake of air above the fluid."

An appreciation of the ill effects of aerophagia and its rational treatment is suggested while considering thoroughly the mechanism of its production. Note first that in most abdominal disorders, however remote, the chief symptom is a sensation of fullness in the epigastrium. This distress signal is interpreted by the patient as "gas on the stomach," calling for action to open an avenue for its escape. This is the origin of belching. Second, it can be dogmatically stated that true gas in the stomach exists only in the presence of pyloric obstruction and increased acid values after hours of fermentation, or following the introduction of an alkali such as Seidlitz powder to an acid medium which forms CO_2. Third, it is important to realize that air is introduced into the stomach normally with each swallow of saliva, food or fluids, the amount accumulated after a meal or drink expanding into a sizable bubble located above the food or fluid level. This is shortly and quite spontaneously eructated or "burped." This phenomenon is best observed during gastric fluoroscopy.

The unnatural introduction or inflation of the stomach with air is due to many and various causes. The most conspicuous examples of inducing aerophagia are exemplified by the infant, breast or bottle fed, which sucks air with its feeding; the youth who discovers that he can accumulate sufficient air by belching to utter weird sounds or guttural sentences; the flighty, nervous, or hysterical individual who uses this means in order to impress its sounds and other effects for the purpose of creating sympathy. Associated with these cases is the complaint of globus. Among individuals with "globus hystericus," it is the desire of the patient to force the "lump in the throat" downward with greater attempts at swallowing than the effortless normal deglutition. The result is a large air bubble in the stomach which is later used in an effort to move the obstruction upward by belching. A vicious circle is created which causes the phantom tumor to persist. Thus two methods of introducing air are demonstrated—the effort swallow, and air suction or belching.

There is a large group of distressed individuals who suffer the effects of belching associated with various gastro-intestinal lesions such as gallbladder disease, and most notably, the functional or irritable colon. Cardiac irregularities, coronary disease, renal and even pelvic disease are conducive to aerophagia. A veteran belcher with a glass of barium behind a fluoroscope demonstrates best the mechanism of aerophagia. One observes first the small air bubbles that follow each other down the esophagus to form the usual gastric air bubble immediately above the food or fluid level; then as the patient is instructed to rid himself of the "gas," action commences. A sucking act starts extra large air bubbles on their downward course which inflate the stomach to an astounding degree, often to twice the amount of ingested barium. Usually after the fifth or sixth effort, air is released and personal satisfaction as to sound effect, volume of gas, and relief is accomplished.

The following symptoms are experienced during the act of belching when the stomach has attained an unusually large size: epigastric fullness, pain, dyspnea to the point where the patient often must sit up in bed and wild-eyed, wonder whence the next breath is to come; palpitation and frequently premature contractions are instigated. The gastric distention also causes marked embarrassment to a decompensated heart, vertigo, hazy vision, dull headache, the frequently described sensation of expansion in the size of the head, numbness, and tingling. Heartburn is noticed because of regurgitated air and stomach contents. The eructation is due to slushing particles of food pitched through a relaxed cardiac valve into the esophagus and mouth.

Deflation brings temporary but grateful relief, usually for half an hour, then the feeling of "gas on the stomach" returns and with it the persistent belching. The false feeling of relief brought about by the relaxation of the overdistended muscular wall of the viscus encourages the repetition of this illogical procedure. When air thus introduced is not expelled via the mouth, it enters the small intestine and by peristalsis is propelled to the colon with consequent colicky pain.

Successful treatment of this baneful symptom calls for a thorough search for the underlying cause and its correction; then of significant importance is the careful explanation of the mechanism of aerophagia, augmented by its graphic description. Belching is a habit and the treat-

ment for the persistent desire to belch is further enhanced by instructing the patient to take five or six deep breaths instead of belching. Sedatives and heat to the epigastrium are indispensable. My results with this method of treatment when dealing with intelligent patients have been gratifying and I recommend its use above all other less effective methods such as a cork between the teeth and abnormal swallowing.

In conclusion, an appeal should be made to the common sense of the patient by a simple explanation and graphic demonstration of the mechanism of aerophagia.

THE DOCTOR OF MEDICINE AND HIS RESPONSIBILITY

ALFRED W. ADSON, M.D.
Rochester, Minnesota

MEMBERS of the North Central Medical Conference, representing the states of North Dakota, South Dakota, Minnesota, Wisconsin, Nebraska, and Iowa, have entrusted me with the responsibility of addressing this National Conference on Medical Service concerning medical problems that are of both local and national interest.

It is the duty of every doctor of medicine to prevent illness, to supply adequate medical care to those who are ill, to perpetuate the science of medicine and to encourage medical investigation. It is true that the average physician would prefer to go unregimented among his sick and administer to their needs, irrespective of race, color, creed, or financial status, rather than busy himself with administrative and political problems. However, since the courts have ruled that group health is a business and have found that medical societies are guilty of restraining trade when attempting to maintain the standards of the practice of medicine, a challenge has been issued to the medical profession: Is there a necessity for lay groups and the Federal Government to take over the control of the practice of medicine?

Has the science of medicine reached its zenith? Have the men and women of medicine become so decadent that they are unable to assume their responsibilities? Are the doctors of medicine no longer able to conduct their practice without government control? Do they lack ability to appreciate their problems? Or are they incapable of constructive leadership in the solution of the numerous responsibilities that are confronting the medical profession today? The reply is, "No."

The science of medicine has been nurtured by men and women who have advanced the knowledge of relieving pain, correcting deformities, lowering infant mortality, prolonging life and preventing illness by sanitary and public health measures. This progress must continue if civilization is to survive.

The medical profession is conscious of social and economic changes and stands ready to cooperate with, and offer leadership to, state and federal agencies in the solution of medical problems. It further believes that better medical service can be rendered by offering advice and leadership to welfare agencies than by serving as a tool under political bureaus.

The medical profession recognizes the necessity of state and federal control of communicable diseases and medical services to inmates of state and federal institutions. It appreciates its responsibility to the Armed Forces and expects to supply the needed personnel. It is willing to coöperate with welfare agencies in providing adequate medical care for the low-income and indigent groups of the population; but in providing this care, it believes that the medical service is augmented when the patient-physician relationship can be maintained by permitting the patient, whenever possible, to choose his own physician. In order to protect the public from worthless, so-called medical procedures and unnecessary operations by unscrupulous individuals, it likewise believes that high standards of medical education and practice must be maintained. This applies not only to the practice of medicine in the office; it applies to the practice of medicine in the humble home or in the most modern hospital.

Although medical education begins in the medical school, it is never completed as long as the physician continues his practice. Medical schools have adopted standards of education and have

Read at the meeting of the National Conference on Medical Service, Chicago, Illinois, February 14, 1943.

required certain courses of study in order that the public might avail itself of the best practices of medicine. Medical licensing boards have further protected the public by requiring of their candidates for licensure prescribed courses of study. State laws governing the practice of medicine and conduct of physicians further protect the public from irregular practices and charlatans.

Medical societies, county, state, and national, have been organized to further the education of the physician by acquainting him with the advances and new discoveries in the science of medicine. They likewise serve as administrative units in the consideration and solution of medical problems. It is obvious that the responsibilities of the respective state organizations are greater than those of the county organizations, and that the national organization is charged with greater responsibilities than those of the state organizations. However, it is also obvious that the activities of all groups must be integrated if medical problems are to be solved effectively. In some states, such as Minnesota, the administrative and the legislative bodies have the confidence of the medical profession. Likewise the medical profession has the confidence of the state administrative and legislative bodies. This confidence has made it possible for representatives of both groups to attack and solve the medical problems which are of mutual interest.

The national organization, through its respective bodies and committees, has conducted an excellent program in furthering medical education. It has crystallized the standards of medical education for the medical student as well as for the practitioner of medicine; it has investigated the claims of new and nonofficial remedies, foods and therapeutic measures and has further protected the public by approval or disapproval of the articles investigated. It has taken active steps through its Procurement and Assignment Committee in providing medical men for the Armed Forces without robbing communities of adequate medical personnel and has made provisions for relocation of physicians where more medical service is needed. It has acquainted the public with the important role that the science of medicine plays in their daily lives, but apparently it has not gained the confidence of the national administrative and legislative bodies that some of the state medical societies have attained. The National Physicians' Committee has made some progress in acquainting the public with the necessity of medical science, but it too had not obtained the confidence of the national administrative and legislative branches of our Government. Therefore, the recent court decision has emphasized the weakness of the educational program so far conducted for the purpose of acquainting the public, the administrative and legislative bodies of certain states, and the national institutions with the important function of the science of medicine in our civilization. It is our duty, as physicians and citizens, to assure those in administrative positions and legislative bodies that we are familiar with the social and economic changes that have thrown greater responsibilities on the medical profession and that we stand ready to coöperate with these agencies in offering leadership in the solution of the numerous problems which nonmedical personnel are trying to solve.

The chief medical problem that concerns doctors of medicine and welfare agencies is that of providing adequate medical care to those who are financially unable to procure this care. This group includes those who are indigent and those with low incomes. Medical care, in its true sense, embraces more than emergency treatment for a particular illness, since it should include a rehabilitation program, such as the correction of deformities and ailments that impair the efficiency of individuals. The rehabilitation program also should include adequate and proper diets, physical training, recreation, protective clothing and housing. In most of the cities the indigent are provided with proper medical care through the charity hospitals, where competent physicians give of their services. This same group in the rural districts is not always so fortunate, since local welfare boards are reluctant to provide this care. It is in these situations that the physicians have been overburdened in assuming all of the responsibilities in providing the necessary medical care. Prior to the more recent economic changes, physicians were willing to assume this obligation because those who could afford to pay for professional services attempted to meet their obligations. However, as a result of the recent social and economic changes, the Government has taken over more and more control of the civilian's activities, and those with moderate and low incomes have been less willing to assume their ob-

ligations of medical care and are insisting that it is the Government's duty to provide medical care and that it is the individual's privilege to squander his extra change.

The problems of this group cannot be solved by physicians alone or by federal, state, and local welfare agencies alone. Ours is a joint responsibility. Conscientious leadership by physicians working in coöperation with county, state and federal agencies can and will bring forth a solution of the problem. Medical service must be rendered, and the physician is willing to give a good portion of his services. But the Government must provide reasonable funds for the care of its indigent, as it must provide for catastrophic illness in the low-income group. Nevertheless, those who come within the low-income group should likewise be made to realize that they too owe a responsibility to their local, state and federal governments and should be encouraged and advised in budgeting their income and expense.

Industrial compensation has accomplished much in providing proper medical care and the necessities of life, during illness, for those employed in industrial institutions. However, there still remains a large group of individuals who receive moderate or low incomes and are desirous of securing the assurance of adequate medical service in the event of illness. Insurance companies have offered this protection through policies covering accident and illness disabilities, but again this protection only partially solves the problem, since many an insuree expects more for his premium than the insurer is able to give. In several states medical societies have attempted to develop medical service plans whereby the insuree may purchase from the doctors within the group full medical protection or medical protection for unexpected, serious illnesses. In some states under the farm security program, experimental medical service plans are being tested out by use in an attempt to find the solution of the problem of supplying medical care to the farmers and their families who are being rehabilitated. In some instances physicians are hired to render medical service to indigent and coöperative groups. Even though physicians, welfare agencies and low-income groups are struggling with the problems of medical service plans, as yet a satisfactory plan for all classes has not been developed. The recipients expect more than the vendors can supply for the premiums paid.

These controversies give rise to discussions on the necessity of compulsory medical insurance. Should such a program evolve, results would be disappointing from the patient's as well as the physician's point of view, because probably the system would be placed under the control of political bureaus, and the patient would be deprived of his free choice of physician.

Therefore, we as physicians believe that a more equitable solution of the perplexing medical problems referred to will be reached if we are permitted to consult and advise administrative officials, legislative bodies, and welfare agencies, since we are more familiar with the medical needs of our respective communities than are those who have a casual knowledge of the medical necessities.

It is befitting to quote the statement found in the opinion written by Justice Miller, of the United States Court of Appeals, of the District of Columbia, in the case of the United States of America versus the American Medical Association, and the case of the United States of America versus the Medical Society of the District of Columbia. The italics are mine.

> It may be regrettable that Congress chose to take over in the Sherman Act the common-law concept of trade, at least to the extent of including therein the practice of medicine. Developments which have taken place during recent decades in the building up of standards of professional education and licensure, together with self-imposed standards of discipline and professional ethics, have, in the belief of many persons, resulted in substantial differences between professional practices and the generally accepted methods of trade and business. As we pointed out in our earlier decision, the American Medical Association and other local medical associations have undoubtedly made a profound contribution to this development. *However, our task is not to legislate or declare policy in such matters, but, rather, to interpret and apply standards and policies which have been declared by the legislature. That Congress did use the common-law test there is no doubt. That Congress was not otherwise advised was perhaps because of the failure of the professional groups to insist upon the distinction and to secure its legislative recognition.*

Does the medical profession of this country need a stronger invitation, or a more direct challenge, to take an intelligent, helpful and fair stand in the enactment of legislation that not only concerns the public welfare but the welfare of medicine itself? Does not the medical profession of this country, as citizens and taxpayers, have a right to express its opinion in these matters before legislation is enacted and rules and regula-

tions are adopted by some bureau? I do not share the opinion that the time for the medical profession to speak up is after such things have taken place. Neither do I have the opinion that Congress would be resentful of intelligent, courageous and fair advice on such matters. What better proof can be asked than the quotation from Justice Miller's opinion that the Court is not responsible for the absence of advice from the medical profession when Congress is drafting a law.

It is not the purpose of this paper to criticize the efforts of our national medical organization nor to criticize the efforts of the National Physicians' Committee, but it is the desire of the members of the North Central Medical Conference to express a wish that a more active program be conducted to acquaint the public, government officials, and legislative bodies with the necessity of medical science and the important rôle it plays in our civilization. It is essential that we as physicians dispel the fear that government administrative agencies and legislative bodies have of our medical organizations and that they be assured of our coöperation in solving the social and economic problems that confront us as a nation.

The functions of acquainting the public on matters of medical interest, assisting bureaus in formulating plans on medical care and offering constructive advice on proposed medical legislation rightfully belong to the national organization known as the American Medical Association. They could be assigned to the National Physicians' Committee, or they might even be undertaken by unifying the activities of the various state committees on public policy and legislation. Representative committees could be appointed for each of the component societies, county, state, and national. These could all be so integrated that national opinion and advice could be obtained and made available for committee hearings on legislation within a few hours' time. Through the national, state, and county committees the entire profession could be informed of proposed medical legislation. Thus, the local constituents of the respective state and federal legislators could express their views before legislation is enacted. Some states already have medical advisory committees from each county. They also have state medical committees on public policy with a physician as part-time executive chairman assisted by legal counsel. A national committee constructed on the same plan as these state committees would have to be created. A physician who has practiced medicine should be chosen as the executive chairman. Both he and his legal counsel would need to be stationed in our national capital. The expense of the national committee on public policy could be financed by one of three agencies, the American Medical Association, the National Physicians' Committee, or the respective state organizations bearing the expense jointly. It would appear more equitable if each physician would be assessed each year for the specific purpose of maintaining a national committee on public policy and legislation.

Our problems are not unlike those of dentists and hospital associations. Therefore, unified effort of medical, dental and hospital associations should further the welfare of the patient.

OBSTETRIC HEMORRHAGE

ARTHUR B. HUNT, M.D.
Rochester, Minnesota

MINNESOTA has always presented an enviable record in its maternal mortality statistics, and yet has shared proportionally in the recent striking decrease in the maternal mortality rate which began in about the year 1933. However, in Minnesota, the rate of maternal deaths from obstetric hemorrhage has, with minor fluctuations, remained practically constant, whereas sharp reductions have taken place in the other two common causes of death; namely, sepsis and toxemia. In Figure 1 this trend is shown in graphic form. The figure records dramatically the unprecedented situation in Minnesota in respect to deaths from hemorrhage, such deaths actually being very slightly in excess of the other two causes in 1941.

The national picture is much the same; that

Included in this paper under this title are only the hemorrhages of the last trimester of pregnancy and intrapartum and postpartum hemorrhage. From the Section on Obstetrics and Gynecology, The Mayo Clinic, Rochester, Minnesota. Read before the meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 30 to July 1, 1942.

is, there has been a small and apparently definite decrease in the number of maternal deaths from hemorrhage, but the decrease is not proportional to the decrease in the number of fatalities arising from sepsis and the toxemias (Table I). The situation may be even more unfavorable than statistics would imply, for it is commonly known that many deaths caused by obstetric hemorrhage are ambiguously reported as deaths by various other titles.

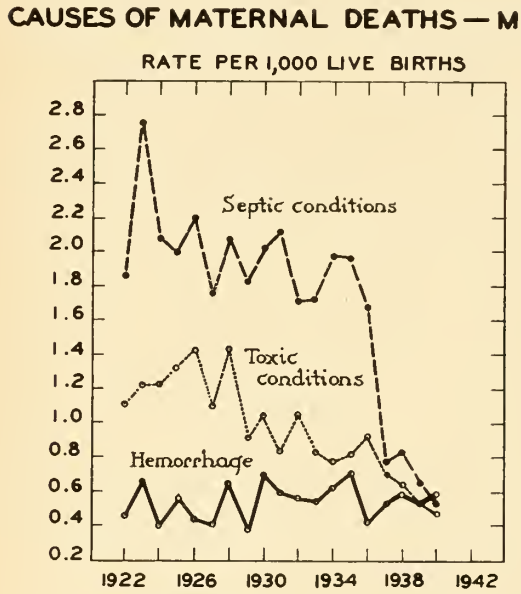

Fig. 1. Graphic representation of maternal deaths in Minnesota in the past two decades (From: Some studies of the results in obstetric and pediatric practice in Minnesota. Division of Child Hygiene, Department of Health, State of Minnesota. Viktor O. Wilson, M.D., director).

Many factors are mentioned as causative of the recent gratifying decrease in the maternal mortality rate. Some of these factors, such as an increase in the number of all confinements attended by physicians, an increase in hospitalization and better obstetric education, should have had a beneficial effect on obstetric risk from the standpoint of hemorrhage, but apparently such is not the case. There has also been a great improvement and simplification in the technic of transfusion. More satisfactory blood substitutes are also rapidly becoming available. In other words, agencies and technics for the reduction of the maternal mortality rate arising from hemorrhage seem to be increasingly at hand, but as yet have had no appreciable effect. It therefore seems timely again to discuss this common obstetric subject and also to suggest that attention now be focused on deaths arising from hemorrhage so that the recent gratifying decrease in the maternal mortality rate can be further accelerated.

TABLE I. TRENDS IN MATERNAL DEATHS*

Death, Causes of	Minnesota: Maternal deaths yearly, mean number		United States: Improvement in recent period, Per Cent	
	1922–34	1935–40	1922–34	1935–40

Total	254	160	37	25

*Data from study of results of obstetric and pediatric practice in Minnesota, Department of Health, Division of Child Hygiene, Dr. Viktor O. Wilson, director.

Material

As a basis for later discussion I shall present a somewhat detailed review of the cases of hemorrhage during late pregnancy in which the patients have been seen in the last ten years in the Section on Obstetrics and Gynecology of the Mayo Clinic. The service is not a large one; there were 5,207 deliveries in the years from 1932 to 1941, inclusive.

About 150 cases that had been tabulated as "hemorrhage of pregnancy" were discarded because, after detailed review of the record in each case, hemorrhage which assumed real clinical importance did not seem to have been present, although no doubt the loss of blood in most cases was in excess of normal limits. There remained 344 cases of true obstetric hemorrhage, or an incidence of 6.6 per cent. In these 344 cases the diagnoses were: placenta prævia, fifty cases (Table II); abruptio placentæ, thirty-five cases (Table III); postpartum hemorrhage, 227 cases (Table IV); and thirty-two miscellaneous cases of hemorrhage (Table V).

Maternal Mortality

There were two maternal deaths in this series: one in 1933 and one in 1936. Both patients died of sepsis rather than of exsanguination. The first patient, a forty-two-year-old primigravida, had bled on several occasions before her admis-

sion to the clinic at thirty-six weeks' gestation. Vaginal examination revealed central placenta prævia. A premature infant weighing 2,340 gm. was delivered by classical cesarean section. The infant survived. The mother died of generalized peritonitis on the fourth postpartum day, after a postoperative course typical of this condition. Necropsy substantiated this diagnosis. The value for hemoglobin twenty-four hours postpartum was 11.7 gm. (77 per cent). The second patient, an octipara thirty-nine years old, was admitted to the clinic, in labor and near term, because of suspected multiple pregnancy or pregnancy complicated by a large ovarian cyst. Before this patient's admission, combined abdominal-vaginal examination had been performed in an attempt to engage a fetal head presenting over the inlet. Roentgenologic examination of the abdomen revealed triplets, with the presenting fetus in vertex presentation and the other two presenting by the breech. Labor was allowed to progress, and after complete dilatation the first baby was delivered spontaneously and the other two by breech extraction. All three infants survived. Severe postpartum hemorrhage occurred very shortly after delivery of the last infant, and since the placenta could not be expressed either by simple expression or by Credé's method carried out vigorously, it was removed manually. The value for hemoglobin reached a low of 5.2 gm. (34 per cent) on the third day, but after blood had been transfused was 8.0 gm. (53 per cent) on the eighth day postpartum. Typical puerperal sepsis developed and the patient died of this condition on the twelfth postpartum day. The pathologic diagnosis at necropsy was "acute endometritis and bronchopneumonia." Both these patients were delivered before the advent of chemotherapy.

TABLE II. TREATMENT OF PLACENTA PRÆVIA AND METHOD OF DELIVERY.
50 cases*

Total	129	Total		100

*Figures pertaining to treatment with ergonovine were taken only from the last five-year period of this study, since ergonovine was not available during all of the period 1932 to 1936.
†In cases in which intra-uterine packing was employed, the morbidity rate was 10.4 per cent, or 8 cases in 77. In the recent five-year series it was only 4.4 per cent, or 2 cases in 46.

had postpartum hemorrhage, on casual survey, there was no increase in the fetal death rate over the total series of 5,207 deliveries. There were five fetal deaths in the group of thirty-two miscellaneous cases of hemorrhage, a rate of 15.6 per cent. Three of these deaths were associated with rupture of the uterus and one was caused by prematurity (weight of fetus, 1,290 gm.) associated with circumvallate placenta. The fifth fetal death occurred neonatally in a premature infant (1,126 gm.), in an instance of suspected abruptio placentæ or miscarriage at thirty-one weeks' gestation. The fetal mortality rate as associated with placenta prævia and abruptio placentæ is discussed herein under the respective headings of the two conditions.

TABLE V. MISCELLANEOUS TYPES OF HEMORRHAGE IN THE LAST TRIMESTER OF PREGNANCY

Bleeding	Cases
Without evidence of placenta prævia	14*
Significant antepartum bleeding without evidence of placenta prævia or abruptio placenta	9†
Due to ruptured uterus	3
Due to circumvallate placenta	3
Due to cervicitis	2
Due to low implantation of placenta	1
Total	32

*In 8 cases a presumptive diagnosis of partial abruptio placenta was made.
†In 2 cases placentagrams revealed normal implantation.

Placenta Prævia

There were fifty cases of placenta prævia, or an incidence of about one in 108 cases, which is somewhat higher than the usual incidence reported. The clinical diagnosis was confirmed by vaginal examination carried out in a sterile manner in all but three of the earlier cases; in these three cases confirmation was made by cesarean section only. Placenta prævia was central or complete in seventeen cases, partial or marginal in twenty-six cases and lateral (just palpable at the edge of the cervix) in seven cases. This classification is based on the results of vaginal examination regardless of the degree of cervical dilatation or effacement found on such examination. There were three sets of twins. In twenty-one cases the fetal weight was less than 2,500 gm. Bleeding was present in all cases, being moderate in eighteen cases, moderately severe in twenty-six and severe in six cases. Some degree of shock was presented by fourteen patients. Twenty-seven patients had estimations for hemoglobin of 10 gm. or less per 100 c.c. of blood, these determinations being taken at least twenty-four hours after delivery. Thirty-eight of forty-six patients did not complete the thirty-eighth week of gestation. Fetal death occurred in thirteen instances among a total of fifty-three babies delivered, resulting in a gross fetal mortality rate of 24.5 per cent. When this gross rate is corrected, to eliminate fetuses that were either dead or expiring on admission of the mothers and those less than 1,800 gm. in weight at birth, the figure decreases to five fetal deaths, or a rate of

).4 per cent. In Table II are shown the obstetric nethods used to control hemorrhage and effect lelivery. Cesarean section, carried out eighteen imes, usually was reserved for central or com-

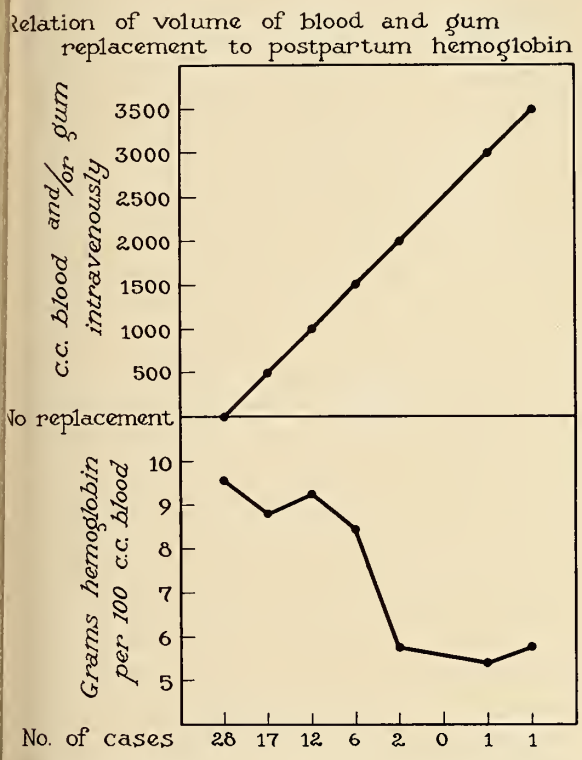

Fig. 2. In this figure it is seen that although patients who have severe hemorrhage receive much larger volumes of blood for replacement, an anemia results which is more severe than that ensuing among patients who have suffered less loss of blood and have been treated by replacement of blood.

plete placenta prævia. It will be noted that in the majority of the remaining cases relatively simple means were required to control bleeding and later to effect delivery. The fact is strikingly brought to attention that when delivery through the pelvis is decided upon, efforts to control bleeding and to effect delivery are not one and the same process, to be carried out simultaneously. It is obviously true that pregnancy is the cause of bleeding in placenta prævia, but it is likewise true that careful, nontraumatic use of such measures as rupture of the membranes or the bag will effectively control the hemorrhage and will do so much more safely than the disastrous assaults on the partially dilated cervix formerly done for placenta prævia.

Abruptio Placentæ

Abruptio placentæ, or premature separation of the normally implanted placenta, occurred thirty-five times during the ten years in question. This condition seems to be encountered with relative frequency among older multiparæ, since sixteen of the thirty-five patients were more than thirty-

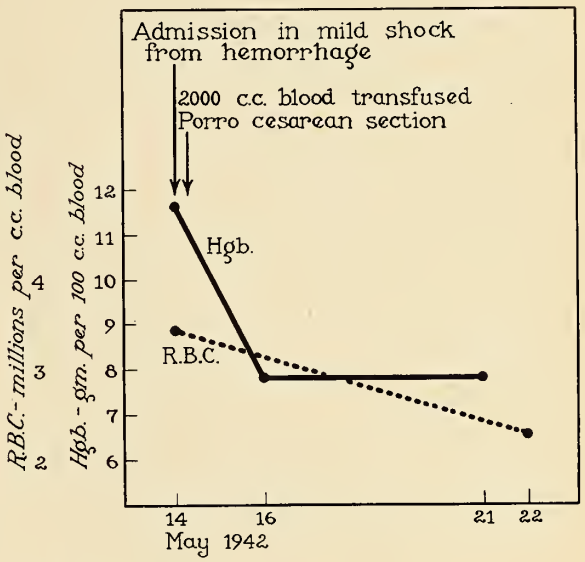

Fig. 3. Determinations of the hemoglobin and erythrocytes of the blood of a patient who had severe abruptio placentæ and hemoconcentration during hemorrhage; days later in the puerperium, after the blood volume adjusts itself, the true anemia of the patient becomes evident in spite of large volume of blood transfused and the not excessive loss of blood at cesarean section in the interim. This illustrates strikingly the fallacy of dependence on determinations of hemoglobin and the erythrocyte count of the blood as guides to loss of blood during the occasional occurrence of severe hemorrhage.

five years old; ten patients had had more than three children; five had had more than six children. A definite toxemia of pregnancy (chronic hypertensive type) occurred among slightly more than half (eighteen) of the patients. The hemorrhage was graded as 1 in sixteen cases, as 2 in ten, as 3 in six and as 3+ in three. In Table III are represented the data on treatment and the method of delivery in these thirty-five cases. The gross fetal mortality rate for the series (thirty-five cases) was seventeen fetal deaths or 48.6 per cent. When this rate is corrected according to criteria noted in the previous section (placenta prævia), the incidence of fetal death is five cases, or 14.3 per cent.

Postpartum Hemorrhage

In Table IV are represented the data on postpartum hemorrhage. It will be noted that in the majority of cases (117) hemorrhage was of grade 1 (estimated loss of blood from 500 to 600 c.c.). The incidence of febrile morbidity for the total of 227 cases, computed according to the

standards of the American Committee on Maternal Welfare, was 13.7 per cent, or thirty-one cases.* It is noteworthy that in the first five-year period of this study the rate of morbidity was 17.6 per cent and that in the latter five-year period the same rate was only 9.9 per cent.*

At the clinic the treatment of postpartum hemorrhage has been rather simple. Many time-honored methods of doubtful value which are still repeated in modern textbooks but which are of little practical use, have been omitted. In the presence of hemorrhage, with a partially separated placenta, if simple expression does not deliver the organ, Credé expression is attempted and if this fails, manual removal is not delayed while the patient bleeds dangerously. The uterus is usually packed if manual removal is carried out. Iodoform gauze for years has proved to be a highly satisfactory material for this purpose. If hemorrhage ensues just after the third stage of labor, the uterus is promptly and vigorously massaged to a state of firm contraction, and if necessary is maintained in this state by bimanual (vaginal-abdominal) pressure while ergonovine is administered intravenously. If atony and significant bleeding persist, the fundus, lower uterine segment and vagina are firmly packed with iodoform gauze. If the uterus bleeds through such a pack, a second one is inserted after removal of the first pack, and if hemorrhage still persists, hysterectomy is considered at once. Obviously, if postpartum hemorrhage is due to operative trauma, surgical repair will suffice to control it, and is the only treatment indicated if the uterus retains satisfactory tone.

Intrauterine Tamponade

Special mention might be made of the rather frequent use of the iodoform pack. Dr. Robert D. Mussey has employed this procedure, on proper indication, since the establishment of the Section on Obstetrics and Gynecology at the Mayo Clinic, and still finds it satisfactory. It is possible that impregnated iodoform, when in the uterus, may actually cause the uterus to secrete into the pack and thus remove bacteria from the uterus. At least, this type of gauze partially soaks up those intra-uterine contents which are in fluid form and when the gauze is removed it helps to rid the uterus of pathogens, if they have been present. Anderson and associates[1] found it fully as effective as the sulfanilamide pack. Only one instance of sensitivity to iodine has been observed in our experience, and this, although it was cause for some concern, was of no serious consequence to the patient. It will be noted in the footnote to Table IV that in seventy-seven cases in which the intra-uterine iodoform pack was used during the complete ten-year period there were eight cases of febrile morbidity, or a morbidity rate of 10.4 per cent, as contrasted with a morbidity rate of 13.7 per cent for the total of 227 cases of postpartum hemorrhage in the series. Likewise, as seen in the footnote to the same table, there were only two cases (4.4 per cent) of febrile morbidity in forty-six cases in which the intra-uterine pack had been used (in the last five-year period under study). Therefore, in the aforementioned five-year period, when the iodoform intra-uterine pack was used in forty-six cases, the morbidity rate (4.4 per cent) was only half that for the total number of cases in the entire five-year series (9.9 per cent).*

We agree with Pastore[2] that the obstetrician should use the so-called radical procedures of manual removal and/or intra-uterine packing as soon as they are indicated, rather than to wait until the patient is in a state of deep shock and nearly exsanguinated. When these procedures are carried out correctly, the morbidity rate is so decidedly reduced that there will be less concern, even though in a few cases packing may be carried out when it might not have been absolutely indicated for the survival of the patients. We feel that proper intra-uterine tamponade not only has saved some patients from death by postpartum hemorrhage but that it has also spared many women the needless loss of large volumes of blood. According to Pastore and our own records, it is the loss of large volumes of blood plus late radical intervention which make for increased morbidity. Vigorous emphasis need hardly be given to the necessity for aseptic technique in invasion of the birth canal, and especially in invasion of the uterus itself. Asepsis should be at least as rigid as that employed when the peritoneal cavity is opened.

Hysterectomy

The rôle of hysterectomy as a procedure for

*The morbidity rates seen as footnotes to Table IV apply only to seventy-seven cases in which packing of the uterus was carried out, and not to the entire series of 344 cases of true obstetric hemorrhage or to the 227 cases of postpartum hemorrhage.

*The forty-six cases in which the intra-uterine pack was used of course are included in the total number of cases in this second five-year period on which the morbidity rate of 9.9 per cent was computed.

the control of obstetric hemorrhage has, to some extent, been neglected in the literature. Seldom is obstetric hemorrhage so severe or intractable as to require removal of the uterus, and yet, perhaps because of this very fact, women afflicted by this type of obstetric hemorrhage often are the ones who die of hemorrhage if hysterectomy is delayed unduly or is not considered at all. Fortunately, most women who require hysterectomy because of tremendous and otherwise uncontrollable obstetric hemorrhage are multiparæ, and hence already have the benefits of living children; but if it appears the patient will die of hemorrhage if removal of the uterus is not performed, it is the physician's duty to disregard parity and to provide her with the one chance of survival which hysterectomy (plus, of course, continuous supportive treatment with transfused blood and other measures) will afford. Hysterectomy was performed without a maternal death in four of the 344 cases of obstetric hemorrhage in the decade reviewed. The indications were: complete rupture of the uterus, two cases; abruptio placentæ, one case; and postpartum hemorrhage caused by uterine fibroids, one case. In the current year of 1942 (which is not included in this survey) it has twice been necessary to resort to hysterectomy, once in the presence of abruptio placentæ and once because of intractable postpartum hemorrhage (but not intra-uterine rupture) in the presence of placenta prævia. The average volume of blood and blood substitutes (excluding fluids such as solutions of sodium chloride and glucose) required to support these patients safely after hemorrhage and hysterectomy was about 2,500 c.c. In one instance the volume required was 4,400 c.c., and in the puerperium the value for hemoglobin was 5 gm. per 100 c.c., in contrast to a value of 14.0 gm. per 100 c.c. before the hemorrhage began. It could thus be estimated that this particular patient lost as much as or more than her total blood volume, but nevertheless survived.

The Rh Factor

Since new knowledge has been gained of the role of the Rh factor in the production of serious reactions to transfused blood, I reviewed the records of the 344 cases of hemorrhage discussed herein from this standpoint. There was only one serious reaction, but the patient was not available, although she is still living, for testing for this factor in her blood. One patient, in her first pregnancy gave birth to a normal infant that survived, but two infants subsequently born to her died of proved erythroblastosis. Blood was transfused without event to this patient during her first pregnancy for severe anemia. The recipient has been recently tested as Rh-negative, and it is planned to test the blood of the donor for the Rh factor, since she lives relatively close to the clinic.

Comment

Assuming that by means of prenatal care constant vigilance is exerted to detect antepartum hemorrhage at an early stage, there remain only two principles the practice of which will satisfactorily reduce the mortality rate of hemorrhage to a bare minimum. These are: the early application of proper and effective obstetric hemostasis and the replacement of blood volume by transfused blood or an acceptable blood substitute to prevent death from exsanguination or shock. The first of these two principles is considered to be the more important.

The methods available for control of various types of hemorrhage have been presented herein, and do not need further repetition except for the reassertion that the safest method for control of hemorrhage often is not one directed toward immediate and perhaps traumatic delivery. The situation is analogous to that in the management of most instances of toxemia of pregnancy, in that, although pregnancy is the cause of the complication, conservative procedures to effect delivery often will produce results conducive to a decidedly lower mortality rate, even though they may require more time and effort on the part of the physician than other procedures would.

The physician can rarely escape the responsibility of dealing promptly and intelligently with obstetric hemorrhage, since almost all impartial surveys of maternal deaths show that the patients nearly always present themselves to the physician at an early time.

Nonobstetric Treatment of Hemorrhage and Shock in Pregnancy

In this section are presented some points in the treatment of the hemorrhage which relate to the restoration of blood volume lost by hemorrhage:

Blood or Blood Substitutes.—These, like any other agents in treatment, should be used in sufficient quantity to obtain the desired therapeutic effect. In this case the desired effect is

to keep the patient out of a state of shock and to relieve serious anemia. Insufficient treatment will result in death of the patient by exsanguination or will leave her barely surviving, with a value for hemoglobin which is dangerously low.

In Figure 2 it is seen that in spite of the fact that this principle was constantly borne in mind, patients who received larger volumes of blood were those among whom anemia was greatest in the puerperium, and the anemia often approached dangerous limits.

Vasoconstricting Agents.—Vasoconstrictors such as 3 minims of epinephrine injected through the intravenous hose are very helpful in initiating the treatment of profound shock, provided the right part of the heart is at once supplied with enough circulating fluid.

Determinations of Hemoglobin and Erythrocytes Valueless.—In some phases of hemorrhage hemoconcentration occurs, so that determinations of hemoglobin and erythrocytes are worthless as measures of the severity of hemorrhage (Fig. 3). The blood pressure is the best indication of shock arising from hemorrhage and of the patient's response to treatment.

Solutions.—Solutions, such as those of sodium chloride and glucose, are not to be depended on for effective treatment of shock and hemorrhage, although they may be lifesaving in maintaining the patient until blood or a good substitute for it can be had. In the presence of excessive hemorrhage and shock any innocuous fluid in the vein is better than none.

Blood Pressure in Shock.—It is a good rule never to allow a patient's blood pressure to remain at so-called shock levels for longer than twenty minutes. Each minute a patient remains in a state of such deep shock that blood pressure cannot be elicited the chance of that patient's recovery diminishes, even though she may be retrieved temporarily from shock.

Presence of Toxemia and Diabetes.—Patients who have toxemia should not be treated with solutions of sodium chloride and patients known to have or suspected of having diabetes should not receive solutions of glucose during an emergency.

Blood Substitutes and Acacia.—Satisfactory blood substitutes are now available in the form of plasma and solutions of acacia and can be used even in rural practice. At the clinic our experience with solutions of acacia has been entirely satisfactory in more than 100 obstetric cases and in general in more than 6,000 administrations of it.

Need for Positive Pressure in Giving of Solutions in Shock.—Patients in deep shock may be found by the usual tests to be without pulse and blood pressure and they may have collapsed veins. It is easy to reach and puncture the veins satisfactorily but solutions will not flow by gravity, positive pressure being necessary. Failure to realize this will waste valuable time while the attendant searches for another vein or cuts down on one. In only one of the cases referred to herein was it necessary to cut down on a vein, although positive pressure was required on several occasions. Failure to recognize this situation has cost the lives of many patients by hemorrhage.

Risk of Transfusion of Blood.—Because the transfusion of blood is associated with a small but definite risk, even in experienced hands, it is a procedure not to be used promiscuously. It is obviously better, when feasible, to avoid the necessity for the transfusion of blood by the prompt institution of effective procedures to control the hemorrhage early and as completely as possible.

Conclusions

Evidence is presented which indicates that the reduction in the number of maternal deaths from hemorrhage has not kept pace with the reduction of maternal mortality from the other two main causes of death; namely, sepsis and toxemia. It therefore appears that there should be an improvement in the use of available obstetric methods for the control of hemorrhage, and especially should facilities for the transfusion of blood and good blood substitutes be made available to the entire population of the state.

Ten years' experience with the hemorrhages of late pregnancy and the puerperium is reviewed. There were two maternal deaths in the earlier half of the series (0.4 deaths per 1,000 deliveries), both of which were caused by sepsis several days after delivery. There were no deaths from hemorrhage directly.

POSTPARTUM HEMORRHAGES AND ASSOCIATED PROBLEMS

HORACE D. McGEE, M.D.

Saint Paul, Minnesota

MOST obstetricians and general practitioners practicing the art of midwifery have been confronted with one or more serious postpartum hemorrhages. Indeed, the anxiety caused by appalling, uncontrollable bleeding has left a vivid, horrible memory to many of them. It requires but a short time on an obstetrical ward to become impressed with the relative frequency of excessive and dangerous blood losses. It is further obvious that estimations of blood loss by many physicians and personnel of institutions are often inaccurate and prejudiced. There is the "too frequent maximum estimation of 500 c.c." when it is obvious to even a casual observer that a more accurate figure would be 1,500 to 2,000 c.c. We believe, therefore, that it is important to report blood loss data from time to time if for no other reason than to encourage the members of the medical profession to become "blood loss" conscious. Suitable measures should then be taken to combat certain evils responsible for the postpartum hemorrhages.

Competent investigators have almost unanimously been impressed with the frequency of the above complication. They all agree that most physicians underestimate blood loss especially when in the hemorrhage levels. Thus, Litzenberg[5] using 600 c.c. as the borderline, finds the incidence as 7.1 per cent. Williams[17] reports a 13 per cent incidence; Peckham,[12] 6.14 per cent; Plass,[5] 9 per cent; Pastore,[10] 6.4 per cent; and Reich,[14] 5.65 per cent. This present report is no exception! We, too, were impressed—and alarmed.

Our series comprises 1,007 consecutive cases, most of which were delivered by interns under the supervision of the resident. It is obvious that certain evils arise when one considers the differences in intellect, ability, and judgment of a large group of interns. Thus, faulty technique in the management of the third stage undoubtedly accounted for some of our hemorrhages. It was noticed that a preponderance of our hemorrhages occurred during the first few days of the change of hospital service. Pastore,[10] likewise, has reported this observation and confirms the statement that experience and ability of the operator and his assistants have a marked effect on blood loss.

It must be admitted that no method of measuring blood loss in the third stage is 100 per cent accurate except by extremely technical chemical procedures. However, an honest attempt at measurement is considerably more accurate than by mere estimation alone. Our method is simple, reasonably accurate, and sterile in that no pans or instruments cause contamination by pressing on the patient's perineum. In our drapes a sterile oiled nonabsorbent paper is folded in the shape of a funnel with the base under the patient's buttocks and the apex toward the floor where the blood is caught in a basin. There is no soaking of drapes and the blood thus caught may be added to the blood expressed with the placenta. In our hands this method has been very satisfactory.

A study of blood loss naturally leads to other associated problems such as the effect of drugs, observations of the placental stage, involution, morbidity, mortality, et cetera. Our series of 1,007 cases were separated into two alternate groups as follows: Group 1 received 1 c.c. of obstetrical pituitrin post second stage, 1 c.c. of hypodermic ergot preparation post placental stage, and ergotrate tablets gr. 1/160 every three hours for twenty-four hours and every four hours for the following forty-eight hours. Group 2 received only 1 c.c. of the hypodermic ergot preparation after the placental stage. An attempt was made to measure accurately the time of placental separation in minutes and seconds by the usual signs such as cord advance, gush of blood, and elevation of the uterus into a globular firm mass. The placenta was then expressed as soon after the separation as possible at the time of a uterine contraction. Failures to observe the process of placental separation and to express the placenta in spite of a relaxed uterus accounted for several of our severe hemorrhages and retained placentas. Retained placentas and hemorrhages were almost uniformly more prevalent during the first week of each service change since supervision was impossible in all cases.

From the Obstetrical Department, Ancker Hospital, Saint Paul, Minnesota.

TABLE I. HEMORRHAGES IN CUBIC CENTIMETER GROUPS

Blood Loss (in c.c.)	Group 1 No. of Cases	Group 2 No. of Cases
600– 700	10	10
700– 800	7	12
800– 900	4	12
900–1000	2	7
1000–1100	6	5
1100–1200	2	2
1200–1300	1	2
1300–1400	1	2
1400–1500	0	4
1500–1600	2	3
1600–1700	2	0
1700–1800	0	2
1800–1900	2	1
1900–2000	0	0
2000–2100	0	0
2100–2200	1	0
2200–2300	1	1
2300–2400	0	0
2400–2500	2	1
2500–2600	1	0
3400–3500	0	1
Total	44	65

Calkins[2] stresses the importance of uterine massage after the placental separation before expressing it. He reports the low average blood loss of 179 c.c. in 800 cases.

Blood Loss

Our results on blood loss were as follows: Group 1 showed an average of 232 c.c. compared to 276 c.c. in group 2 or an average of 254 c.c. for the entire series. In group 1 there were forty-four hemorrhages of 600 c.c. or over for an incidence of 8.6 per cent while in group 2 there were sixty-five hemorrhages for an incidence of 13 per cent. The average incidence in the two groups was 10.8 per cent. This figure is somewhat higher than that reported by other observers, but is below William's[17] figure of 13 per cent. Table I groups the hemorrhages into 100 c.c. columns.

TABLE II. CAUSES OF THE HEMORRHAGES

	Group 1	Group 2
Atonia alone	20	32
Atonia, episiotomy and lacerations	3	2
Atonia and cervical lacerations	2	2
Atonia following abruptio placenta	5	2
Retained placentas	4	15
Adherent placentas with manual removal	3	2
Retained placentas due to pituitrin	4	0
Low implantation of the placenta	0	1
Placenta Praevia	0	2
Retained membranes	0	2
Laceration of the cervix	0	2
Episiotomy	0	1
Caesarian section	1	0
Cause unknown	2	2
Total	44	65

As would be expected most of the above hemorrhages were in the 600-700 c.c. group. It is interesting, however, to notice the astoundingly high blood loss of 3,400 c.c. in group 2 and the frequency of hemorrhages in the 2,000-2,600 c.c. group. In spite of such appalling hemorrhages there were no maternal deaths from this cause and it is interesting to note that the patient often exhibited little or no evidence of shock despite the losses reported. However, because of the possibility of secondary manifestations of shock, intravenous fluids were started early and blood cross-matched immediately. An effort was then made to replace the lost blood as soon as possible. In no case was uterine packing performed thus suggesting that this dangerous procedure is seldom required.

In ascertaining the causes of hemorrhage it must be acknowledged that certain overlappings occur. Thus, Table II attempts to classify the causes of hemorrhage into various groups.

From the above chart it is apparent that atonia was the preponderant cause of hemorrhage in both groups. In fact, this one factor accounted

for nearly half of the cases. It is evident that much of this group can be eliminated by proper management of the third stage. This may be accomplished by intensive teaching of our medical students and interns. It must be emphasized that expression of the placenta without uterine contraction is extremely dangerous and undoubtedly the cause of many unnecessary postpartum hemorrhages.

Pituitrin after the second stage has often been accused of causing retained placentas by contraction of the lower uterine segment before the placenta is expelled. In our series there were four cases attributable to this medication of which none was serious. On the other hand there were fifteen retained placentas in group 2 which received no pituitrin. If the four retained placentas due to pituitrin are added to the four other cases in group 1 there is still a preponderance of retained placentas (fifteen to eight) in the group receiving no pituitrin. This would seem to indicate that pituitrin has a beneficial effect after the second stage in a certain number of cases in which separation and expulsion of the placenta is delayed.

Our series indicate that long labors due to abnormal presentations, contracted pelvis, et cetera, markedly increases the blood loss. Thus, in posterior presentations the average blood loss was 415.6 c.c. compared to 254 c.c. in the entire series. The first stage averaged 11.77 hours in the entire series compared to 17.6 hours in posteriors while the second stage was 43.5 minutes compared to 1 hour 31 minutes in posteriors. This observation is contrary to that expressed by Calkins[3] who considers posterior presentations normal. He finds very little difference in the length of labor in anterior and posterior presentations. He[4] further states that the length of labor has no influence on the amount of blood loss in the third stage. Our experience, however, has taught us to respect long labors if for no other reason than the danger of hemorrhage—and this in spite of rests, fluids, and adequate nursing care. Calkins does emphasize a point, however, to which we fully subscribe, namely the marked influence of ether and other gas anesthetics on the blood loss. We, like he, advise the discontinuance of anesthesia after the second stage as soon as possible in order to allow the uterus to contract firmly. If anesthesia is required later for the repair or other procedures it may be readministered.

In summarizing this part of this report we wish to emphasize once more the remarkable tolerance of pregnant women towards blood loss. Their apparent plethoric state has been verified time and again. This single factor has allowed many physicians to "get by" when they estimated the blood loss at 500 c.c. It is important to remember that shock rarely or ever occurs from a blood loss of 500 c.c. unless accompanied with other complications. Thus, when an obstetrical patient is in shock in spite of average blood loss, one must think of other complications such as ruptured or inverted uterus, embolism, heart failure, et cetera.

Placental Separation

Various reports on the timing of placental separation are found in the literature. The older works almost uniformly reported longer placental stages than the more recent investigations indicate. Thus, until the past few years students were taught that this stage lasted fifteen to twenty minutes. Recent observations show that the placental separation is often simultaneous with the second stage or in the first minute thereafter. Davis and Boynton[7] found that when intravenous ergot was injected at the time the anterior shoulder was brought into view, the placenta was delivered in less than three minutes in 754 out of 1,020 cases. However, when the ergot was not given until after the placenta was delivered the placental stage was usually over four minutes. In our series the average time of placental separation was 4.17 minutes, being 3.5 minutes in group 1 and 4.84 minutes in group 2. It must be realized that this difference in the two groups is probably not due to pituitrin since the action of pituitrin intramuscularly is not obtained until 3 to 5 minutes according to Davis.[6] It can further be stated that a great number of the placentas in both groups separated immediately or in the first minute but that a few retained placentas made the average much higher than usually obtained.

In spite of the usual text book signs of placental separation, it is not always easy to determine this phenomenon. We are certain that in some cases hemorrhage was caused by too hasty expression with resulting partial separation and atonia of the uterine musculature. However, many hemorrhages were also caused by "too late" expression with a resultant filling of the uterus

with blood back of the placenta. The old teaching of waiting for the mother to expel the placenta is not justified. There is danger of contamination and excessive fatigue in a patient who is already exhausted in most cases. The patient is anxious to rest and a simple expression will allow her to return to bed. In most cases the placenta was easily expressed. In others, supposedly retained placentas were expressed with little difficulty by the resident though the intern encountered difficulty due to inexperience. Some of the retained placentas occurred in obese women the obvious difficulty simply being failure to palpate the uterus. We encountered no inversions of the uterus or other unfavorable complications by our expression technique. Occasionally the cervix was pushed downward too far so that it presented at the introitus. By simply inserting the hand downward above the symphysis the uterus could usually be brought to a higher position. It was noticed that unless the uterus was thus replaced bleeding was often quite profuse.

Morbidity

A study of blood loss necessarily involves a determination of morbidity. Our definition of morbidity is commonly cited and so any patient with a temperature of 100.4 on any two days of the puerperium after the first twenty-four hours is considered to have a morbidity. In spite of our high incidence of hemorrhages our morbidity was only 4.75 per cent and was approximately the same in both groups. This figure compares very favorably with the reports in the literature and includes any condition causing fever in the puerperium. No attempt was made to exclude upper respiratory infections, pneumonia, pyelitis, or other incidental infections. Peckham and Kuder[13] report a clinic morbidity of 17.10 per cent with 39.62 per cent for operative procedures and 24.46 per cent for spontaneous deliveries with hemorrhage. Our low morbidity is undoubtedly due to several factors. The most important one is that very conservative obstetrics is practiced, forceps of any kind being applied only when indicated and after consultation with the attending man. Vaginal examinations are prohibited unless necessary, all visitors (including the husband) are barred, and all unnecessary procedures are discouraged. We attempt to replace blood in those who have obviously suffered from hemorrhage or whose hemoglobins are unnecessarily low. Lately the sulfonamide group of drugs has helped our records. It is interesting to notice that the morbidity in the two groups was similar, indicating that perhaps the routine use of ergot preparations in the postpartum period is of doubtful value from this point of view.

Involution

This study was undertaken primarily to evaluate the effect of ergot in the postpartum period. Thus, group 1 was given ergotrate gr. 1/160 every three hours for twenty-four hours and then gr. 1/160 every four hours for the next forty-eight hours. Group 2 received no ergot preparation whatsoever. On the day of discharge the height of the fundus above the symphysis was accurately measured in centimeters. Interestingly enough, no beneficial effect was noticed in group 1. Thus, in group 1 the height of the fundus was 6.18 cms. on the eighth postpartum day and 5.61 cms. on the ninth day while in group 2 it was 6.29 cms. and 5.79 cms. It should not be difficult to understand why there is little or no difference. In fact one might argue that perhaps ergot slows involution by causing excessive contraction of the uterine musculature with an obvious local anemia due to constriction of the blood vessels. Galloway[8] considers involution as the most important physiologic change taking place in the puerperium and agrees with Teacher and Wormser[15] that the most important factor in involution is proper separation of the placenta with complete removal of all the products of conception. Adair, Davis, Kharasch, and Legault,[1] working with ergotocin, concluded that in all instances the process of involution was hastened or favored by the use of this preparation. They also stated that in infected cases ergotocin seemed to hasten expulsion of the lochia, increased contractions, and helped involution. We, however, have failed to substantiate this finding, our infected cases showing just as rapid involution as the clean ones provided all the products of conception were removed. Kronig, in 1901, held that infection does not interfere or delay the regeneration of the mucosa. Williams'[18] observations indicated that neither the existence of moderate infection nor retention of fetal tissue following abortion or full term labor seriously interfered with regeneration outside the placental site although def-

initely delaying the involution of the latter. He showed that the placental site usually disappeared about the seventh postpartum week while outside the placental site the mucosa was completely restored by the fourth week.

Postpartum examinations at six weeks failed to reveal a difference in involution of the two groups. Thus, the number of subinvolutions, retroversions, erosions, etc., were approximately the same in each group. One interesting observation was that the duration of the red lochia is considerably longer in both groups than previously taught. In many of our patients the red lochia persisted for three to four weeks even though involution seemed to be normal at the six weeks' examination. Often the red lochia returns after the patient resumes her duties at home and may persist three to six weeks in extreme cases. Moir,[9] studying 250 patients, found the average duration of red lochia to be twenty-four days in contrast to previous teaching of four to ten days. In his series subinvolution and retroversion did not prolong the red lochia stage. Nursing, age, and parity likewise had no effect.

In group 1 complaints of after-pains were much more frequent than in group 2. In a few cases the pains after the administration of ergotrate were so severe that the patient requested its discontinuance. Primiparous women seldom complained of after-pains in either group, an observation often confirmed.

Drug Reactions

Before the routine use of any drug is prescribed a thorough study must be made as to its toxity, untoward reactions, and danger to life. It is important and imperative that all untoward reactions be reported to the medical profession. Though we had no deaths from the administration of drugs, the anxiety and worry caused by certain reactions warranted extreme caution before the use of routine pituitrin or ergot, especially by the intravenous route. In two cases our hypodermic preparation of ergot caused extreme shock, skin manifestations, dyspnea, and other side reactions. In three cases ergotrate tablets had to be discontinued because of severe pains in the legs. That the fluid extract of ergot is dangerous is indicated in the unpleasant reactions of nausea and vomiting and the state of ergotism and dry gangrene of the extremities with prolonged administration. Thus, Welkoff and Ferguson[16] reported bilateral dry gangrene of the legs after the patient had taken two fluidounces over a five-day period. Davis and Boynton,[7] studying ergonovine, state that this drug has no undesirable reactions regardless of the mode of administration. This statement seems dangerous, however, since some individuals may be allergic to any vegetable product. It is true that they may not have encountered any reactions in their relatively small series but such a statement seems unlikely to hold in a larger group. Just one death from a routine drug would justify its discontinuance unless the effects through reduction in blood loss and hemorrhages markedly offset this danger.

Pastore,[11] working with intravenous pituitrin (1.5 minims of surgical pituitrin in 2.5 c.c. normal saline), had 5 cases of pituitrin reaction out of ninety-six cases with one death. In patients with hypertension pituitrin causes marked elevation of blood pressure and also causes urinary retention according to Davis.[6]

Would it not be safer to reserve intravenous ergot and pituitrin to those relatively few cases of atonia which can't be controlled otherwise? Our unfortunate reactions have encouraged us to assume a skeptical attitude.

Mortality

There was one death in this series—a five and one-half month probably self-induced abortion of a hydrops fetalis fetus, retention of the placenta, manual removal of a necrotic, edematous enlarged placenta, severe transfusion reaction, and death on the third postpartum day from gas bacillus infection (B. Welchii). This patient had severe abdominal pain, rapid pulse, and a temperature of 102.4° before delivery indicating that perhaps the patient had the infection prior to delivery. It was difficult to determine whether the symptoms after delivery were due to the gas bacillus infection or to the transfusion reaction since both are similar.

Fetal Mortality

The fetal mortality in this series was only thirty-eight in 1,007 coses. Thus, there were ten macerated fetuses, seven stillborn intrapartum deaths, fourteen premature neonatal deaths, and five neonatal term births. Of these, fifteen were under 3 pounds, the smallest weighing only 380 grams. Any fetus 27 centimeters or more was

used in the statistics and was reported to the state board of health.

That conservative obstetrics was practiced is evident since only three cesarean sections were performed and that 945 out of 1,007 cases were allowed to deliver spontaneously. This fact alone is meaningless unless the fetal and maternal mortality and morbidity are correspondingly low. Since in this series both the maternal and fetal mortality *were* low we wish to emphasize the well-known observation that conservatism in obstetrics pays the highest dividends in the final analysis.

Conclusions

1. Estimations of maternal blood loss are inaccurate. There is a tendency to underestimate excessive losses and to overestimate minimal amounts.

2. Pregnant women seldom show clinical signs of shock unless blood loss is excessive (usually over 1,000 c.c.) unless other factors such as trauma, anemia, malnourishment, etc., are also present.

3. In our series hemorrhages over 600 c.c. were encountered in 10.8 per cent of our cases.

4. Hemorrhages occurred 4.4 per cent less in cases in which pituitrin was used after the second stage than in those in which none was used.

5. Our average blood loss was 254 c.c., being 44 c.c. less in the group receiving pituitrin.

6. Long labors from any cause tend to increase the loss of blood.

7. Blood loss should be replaced as soon as possible to reduce morbidity, secondary shock, and to prevent anemia and subsequent complications.

8. Uterine atony accounted for approximately half of all our hemorrhages.

9. Most placentas separate in less than one minute. The average time in our series was 4.17 minutes but this average is erroneous since a few retained placentas markedly increased the average.

10. Pituitrin by hypodermic injection had little or no effect on placental separation since most of the placentas were separated before the pituitrin had time to exert its effect.

11. Timely expression of the placenta is beneficial to the patient both in the reduction of blood loss and in allowing the patient to return to bed for needed rest.

12. The routine use of ergot has its doubtful value since in this series it failed to lower morbidity, failed to encourage involution, was responsible for severe after-pains, and in a few cases produced serious reactions.

13. Pituitrin must be used with extreme care since severe reactions are not uncommon.

14. The maternal mortality was 1 death in 1,007 cases, a 5½ month probably induced abortion, the patient dying from gas bacillus peritonitis and transfusion reaction.

15. The fetal mortality was 38 cases in 1,007. Fifteen of these were under 3 pounds, ten of them being macerated.

16. The maternal morbidity was only 4.75 per cent, conservatism being responsible mainly in obtaining this low figure.

17. By reporting blood loss series it is hoped that the medical profession will become more "blood loss" conscious.

DELAYED SPEECH FROM THE STANDPOINT OF A PSYCHOLOGIST

GRACE ARTHUR, Ph.D.
Saint Paul, Minnesota

IT IS not surprising that parents, teachers and even physicians become alarmed when a child fails to develop satisfactory speech habits at about the normal age. In a large percentage of several hundred cases of delayed speech observed, the slowness in learning to talk was symptomatic of slowness in general intellectual development. Sometimes the total picture was one of slower development than that of the average child, physically and emotionally as well as intellectually.

The histories of these cases showed unexpected variety. They included: birth injuries; brain tumor; encephalitis lethargica; poliomyelitis; epilepsies; poor general constitution, with lack of speech drive only one of many lacks; mutism, with speech drive reduced almost to the vanishing point; family histories of speech disorders of various kinds; hereditary feeblemindedness; glandular imbalance; defective hearing; mongoloid characteristics; structural anomolies that made the taking on of speech habits more difficult than for the average child; and various other conditions too numerous to tabulate.

The subsequent histories of these cases were as varied as those preceding examination. A very few made normal recoveries without special help. The majority continued to show retarded mental development, but in time developed some speech. Only a few failed to learn to say a few simple words. Of these few, only one was under immediate supervision from infancy to adolescence. This case had been diagnosed as an encephalitis shortly after birth.

Because of their good nature, children with mongoloid characteristics appear to be more trainable than certain other types. Glandular imbalance, slow general development accompanying prolonged illness during the first few years of life, defective hearing, and oral inactivity in children otherwise normal seem to be the conditions accompanying the delayed speech cases that respond best to therapy.

One child who earned a borderline rating (I.Q.78) on a Binet scale at the age of six, was helped to make a normal adjustment as speech cleared and at the age of ten was doing better than average school work with a Binet I.Q. of 106. Another child with about the same rating (I.Q.80) seemed more promising. The mother's attention, however, was absorbed by twin babies, and by the time she became alarmed enough to try to coöperate in plans for therapy, habits of non-understandable speech were so firmly fixed that little could be accomplished. Intelligence ratings on the Binet scales drop rapidly when the child cannot talk understandably, and so this child, by the time she reached adolescence, had earned a succession of feebleminded ratings that resulted in her placement in a school for the subnormal.

A duller child than either of these received intensive training over a long period. She not only learned to talk understandably, but made a comfortable school and social adjustment with a group several years younger than herself.

Because of the influence of speech upon Binet ratings, it is difficult to make a correct diagnosis for a non-talking child without the use of a nonverbal scale. Two children in the group had narrowly escaped commitment as feeble-minded on the basis of low ratings given them by examiners inexperienced in dealing with cases of delayed speech. One of these, with a Binet I.Q. of 110 is now in a junior high school. The other is in high school. He has a Binet I.Q. of 119, and an I.Q. of 141 on the Point Scale of Performance Tests. This is significant, as many cases of oral inactivity are non-verbalists in contrast with stammerers, who often tend to be highly verbalistic.

Another child with extreme oral inactivity earned a low average rating (I.Q.88) on the Kuhlmann-Binet Scale at the age of four. The mother was interested and intelligent enough to carry out detailed instructions. By the time this child was ready to enter the second grade, the rating had increased to "very superior" (I.Q. 136). Stammering is not unusual at one stage of recovery from severe oral inactivity, but may be temporary if recognized for what it is and given appropriate treatment. This child stammered for several months. The mother was con-

scientious in carrying out instructions. Since the stammering cleared, speech has been normal and school progress much better than that of the average child.

Whatever help is to be given the non-talking child should be given during the early years of rapid development. Therapy planned for the child with a poor speech drive is quite different from that given the child with a strong speech drive who is having difficulty in making himself understood.

Whatever the causative factors, the adjustment of the child with delayed speech needs to be watched. Help should be given until a satisfactory social and academic adjustment has been made. The nature of the adjustment depends upon many factors. For some children, the only comfortable adjustment will be in a school for the subnormal. For others, it will be college with honors. The important thing is for each child to get the help that he needs in time to enable him to develop whatever potential abilities he may possess.

Summary

In a large percentage of several hundred cases of delayed speech, slowness in learning to talk was symptomatic of slowness in general intellectual development.

The histories of these cases are varied. They include birth injuries, glandular imbalance, structural anomalies, defective hearing, oral inactivity and other conditions too numerous to tabulate.

In some cases normal speech developed. Only a few failed to learn at least a few simple words. The majority developed simple but understandable speech.

Because of their good nature and willingness to coöperate, children with mongoloid characteristics are often more trainable than other types.

Glandular imbalance, slow early general development resulting from prolonged illness, defective hearing, and oral inactivity in children otherwise normal appear to be among the conditions that respond best to therapy.

Because of the influence of speech upon Binet ratings, there is danger in using these scales as a basis for diagnosis in cases of delayed speech.

Whatever help is to be given the non-talking child should be given during the early years of rapid development.

It is important for each child to get the help he needs in time to enable him to develop whatever potentialities he may possess.

VITAMIN A IN THE TREATMENT OF HYPERTENSION

JACOB S. BLUMENTHAL, M.D. and MACNIDER WETHERBY, M.D.
Minneapolis, Minnesota

AT times hypovitaminosis of several of the vitamins has been reported as a possible factor in the causation of hypertension. There has been very little substantiating evidence but vast quantities of vitamins have been sold on this basis. Juan Govea Peña and M. Villaverde[2, 3, 4] of Cuba have recently reported on the use of vitamin A in large doses in hypertension. They rationalize this treatment by citing the work of Herfort[1] who states that vitamin A exercises a stimulating effect upon the internal and external secretions of the pancreas. They then state that assuming that these secretions contain hypotensive hormones, vitamin A would then exercise the same hypotensive action indirectly by exciting production of such hormones. These authors then further report that they have studied the content of vitamin A and total carotinoids in the blood of chronic arterial hypertensives and have found a low content of this vitamin. Sixty-five cases are reported as being treated. The dose was 180,000 international units daily for two weeks followed by maintenance dose of 90,000 international units daily. A drop in blood pressure was noted as long as the medication was continued. The hypotensive action of this medication was then declared to have been "not only undeniable but remarkable." Only four out of

From the Department of Medicine, University of Minnesota.

sixty-five cases and these of malignant hypertension were not benefited.

This report is on the result of the use of vitamin A in large doses in twenty cases of hypertension followed at the University of Minnesota. These patients were not selected. They were taken consecutively. Their chief complaints were headache, dizziness, and dyspnea on exertion. They were not decompensated. No marked coronary diseases were included in this series. These cases were given capsules containing 50,000 international units of vitamin A each. 200,000 international units of vitamin A were given daily. This dosage was continued for two weeks and followed by a maintenance dose of 100,000 international units daily. The average period of treatment was eight weeks. There were six males and fourteen females. Ages varied from thirty-one to sixty-nine years. The average period of known hypertension was seven and one-half years. In all cases many blood pressure readings were taken to get an average and all readings were taken under similar circumstances before and after treatment. Subjectively, six patients said they felt better but this improvement had no apparent relation to the blood pressure. The trend of readings as shown in the table, did not give evidence of any action on blood pressure whatsoever. Our findings did not corroborate the reported hypotensive action of vitamin A.

The systolic blood pressure determination of these twenty hypertensive patients after treatment was of a higher average in eleven cases and lower in nine cases. The diastolic blood pressure was of a higher average in nine cases, lower in eight cases and the same in three cases. There was no striking evidence of any changes in blood pressure following therapy other than the usual variations in readings.

Summary

Vitamin A* in doses up to 200,000 international units daily for two weeks followed by 100,000 international units daily for six to twelve weeks did not have any significant effect on the blood pressure determination of twenty hypertensive patients.

*Vitamin A furnished through the courtesy of J. B. Roerig and Co., Chicago, Illinois.

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL

A. J. Hertzog, M.D., and S. V. Lofsness, M.D.
Pathologists

Presentation of a Case

Dr. Petit: The case this morning is that of a white man forty-eight years old who was admitted to the Medical Service of this hospital for the first time on February 16, 1943. His present illness began three days before admission when he noted fever, malaise, anorexia and cough. Within a few hours he began to have chilly sensations and felt feverish. His coughing increased and he began to raise a small amount of blood-streaked sputum. His breathing gradually became more labored, and he noticed sharp pain in his right chest associated with respiration to some extent. During the evening of February 16 his temperature rose to 105 degrees, so he was brought to this hospital. His past history is of importance in that he stated that he had had heart disease for twenty years. A physician examined him and told him he had a murmur, and since then he has been taking digitalis. He has had intermittent palpitation and mild shortness of breath on exertion, but has never had edema of his legs. He operated a small restaurant until one year ago, but since then has been unemployed. However, he was active until a few days ago, and his cardiac symptoms have remained mild. He stated that he has never had rheumatic fever or syphilis.

On admission his temperature was 103.8 degrees, his pulse rate 100, respiratory rate 24 and blood pressure 150/74. He was flushed and dyspneic, coughed frequently and appeared seriously ill. Examination of the head and neck was essentially negative. His heart appeared to be markedly enlarged and its rhythm was totally irregular. A loud rough systolic murmur was heard over the entire precordium, especially over the aortic area, and it was transmitted into the neck. A systolic thrill was palpable at the base of the heart, and a high pitched early diastolic murmur was audible to the left of the upper part of the sternum. His venous pressure was 9 cm. of water. Crepitant râles were heard throughout the left lung field, especially over the upper lobe, and in this region the breath sounds were diminished and of bronchial type. There were a few scattered râles and rhonchi over the right lung. His abdomen was moderately distended and tympanitic, but was not tender and no masses were felt. Rectal examination was negative, and no abnormalities were noted in his extremities. A tentative diagnosis of left upper lobar pneumonia and rheumatic heart disease was made.

Laboratory studies revealed the following information: Hemoglobin 90 per cent (Sahli); leukocyte count 10,500 with 68 per cent neutrophiles; Kline negative; and urinalysis negative. A sputum sample contained pneumococcus type IX. A cardiogram showed left preponderance, auricular fibrillation and changes in the T-waves suggesting myocardial damage. An x-ray of his chest showed a large heart of the left ventricular type, and extensive consolidation of the left upper lobe.

He was given 4 grams of sulfathiazole, followed by one gram every four hours. He had been taking one grain of digitalis daily and this was continued. Shortly after admission he was placed in an oxygen tent. After 12 hours his temperature fell to 101 degrees, but the next morning it again rose to 103 degrees and remained high until his death. He gradually became more dyspneic, râles were heard over both lungs and he died on February 19, 1943, three days after admission. A blood culture drawn on the last day was negative.

Dr. Hertzog: This man had pre-existing heart disease and developed lobar pneumonia from which he failed to recover. Dr. Peppard, have you any comments?

Dr. Peppard: This man evidently died from lobar pneumonia. We still have an appreciable death rate from that disease, especially in people with complicating diseases and in the older patients. If this man had been seen earlier, he might not have died. Recently, in this hospital, we have had several deaths from lobar pneumonia in men who were chronic alcoholics and had fatty livers. It is well known that they have markedly reduced resistance to infection. This patient had an associated heart disease. From the story, it was probably an aortic lesion, with stenosis and insufficiency. He may have had an associated mitral deformity—many of them do. He gave no history of rheumatic fever, but that is true of many persons with rheumatic heart disease.

Dr. Hertzog: Dr. Arthur will now present the autopsy findings.

Dr. Arthur: The most interesting findings were in the chest. The left lung weighed 920 grams. Its upper lobe was firm, red and airless; pus could be expressed from the small bronchi. The lower lobe was only slightly congested. The right lung weighed 1030 grams. It was diffusely congested and edematous. Each pleural cavity contained approximately 200 c.c. of cloudy tan fluid.

When the breast plate was removed, it was noted that the internal mammary arteries were significantly dilated. A finger was inserted into the aorta through a small incision and an obstructing lesion was felt in the arch. The pericardium was slightly thickened and fibrous with a few thin calcified plaques, and it was densely adherent to the heart. It was also firmly adherent to the medial surface of the left lung and to the diaphragm. The pericardium, heart and great vessels were removed together, and the heart is esti-

HISTORY OF MEDICINE IN DODGE COUNTY

BY JAMES ECKMAN

Rochester, Minnesota

and

CHARLES E. BIGELOW, M.D.

Dodge Center, Minnesota

(Continued from March issue.)

Milton Township, named for John Milton (1608-1674), was organized on May 20, 1858,[5] and **Dr. John Quincy Adams Vale** (1825-1903), who eight years previously had been practicing medicine in Meigs County, Ohio, was elected first chairman of the board of supervisors. He was reëlected to this post in 1859.[5] Doctor Vale was in every respect a pioneer, and had been in Pine Island in 1855, but how he happened to be in Milton Township in Dodge County in 1858 is not known. He moved to Homer in Winona County in 1861, and there he died on September 3, 1903, as will be shown later.

Indians inflicted neither death nor injury on the pioneers of Dodge County, for by the time the settlers arrived the red man had been driven far to the west, except for a few occasional bands of wandering savages who were beggars rather than marauders. Yet, if one story can be believed, Dodge County was the first to learn that the fearful massacre of 1862, in which **Dr. Otis Ayer** (1817-1889,[23] **Dr. Asa Wilder Daniels** (1829-1923),[24] Dr. **Jacob W. B. Wellcome, Sr.** (1825-1906)[25] and others rendered such signal medical and surgical services, was contemplated by the Sioux. An old resident of Dodge County once recalled:

> In February, 1862, a Winnebago and his family stopped with us over night, on their way to Wisconsin. In his broken dialect he said to us: "Sioux kill white man! Sioux kill Winnebago! Grass—pony—eat!" By questioning we ascertained that what he wished to communicate was, that when the grass had grown sufficient for their ponies to live, the Sioux were coming to kill the white men and Winnebagos, and he and his family were fleeing from what we then thought imaginary danger, and so gave his story no particular credence; yet it proved to be the first intimation of the terrible massacre which occurred the following summer.[14]

The War and the Railroads, 1860-1870

The tempestuous years immediately preceding the War of the Rebellion and those of the war itself seem not to have deterred physicians from locating in Dodge County. **Dr. John Jacob Everhard** (1829-1908), a graduate of the Rush Medical College of Chicago in the class of 1856, settled in Mantorville in 1860, and remained there until 1874. One of his first patients when he arrived in the town was a person who had been bitten by one of the rattlesnakes previously mentioned. Doctor Everhard was joined two years later

by **Dr. Jasper Bedient** (1838-1920), a native of New York State who had been graduated from the Berkshire Medical College of Pittsfield, Massachusetts, in the class of 1860. Doctor Bedient settled in Mantorville, but he was to spend most of his life in Kasson.

In certain sections of Dodge County there was opposition of some degree to the draft during the War of the Rebellion, but the services of the county's physicians in this war seem to have been creditable. Only one, so far as is known, gave his life in the struggle. This was Dr. Augustus O. Potter of Mantorville, who had come to that town before the outbreak of the war, as previously mentioned. He joined the Sixth Minnesota Regiment of Volunteers as assistant surgeon. The Adjutant General's Office of the War Department[26] has reported that Dr. Potter died of disease at Helena, Arkansas, on September 13, 1864. He was an unusually skilled physician and surgeon, and was reputed to have risen rapidly in the army.

Dr. Edward P. Kermott, then of Wasioja, enlisted in Company C of Dr. Potter's regiment in 1864. He served as a private soldier, but before he was mustered out he was promoted to the rank of corporal, as will be shown later.

Doctor Dartt also enlisted as a private soldier. Eventually, he gained the rank of captain of his company. He served in Company A of the Fifth Minnesota Regiment of Volunteers, formed in May of 1862. He thus took part in such events as the Siege of Corinth and the Battle of Iuka; but he resigned his commission on April 12, 1863, because of poor health, and returned to Mantorville. So far as is known, he never again practiced medicine, but turned his interest toward farming and other pursuits.

Dr. James A. Garver served with Indiana regiments, as will be shown later.

Dr. James Mansfield Ryder served in the War of the Rebellion as a private soldier in the Fifth Minnesota Regiment of Volunteers. He was discharged for disability in December of 1862, and returned to Milton Township.

Doctor Everhard remained in the county during the war. It is believed that he had not been able to satisfy the requirements of the physical examination, for some reason.

The melancholy medical history of one resident of Dodge County during and after the War of the Rebellion has been recorded, and it is quoted as it was written:[27]

> He had been struck by a bullet in the left groin, and after cutting the neck of the bladder and crushing through the pelvis bone, it lodged in the right hip. For eight days our boys lay on the field, suffering, in addition to their wounds, the pangs of thirst and starvation. After staying a few days at Centerville, Mr. White proceeded to Fairfax Seminary hospital, and was discharged in November. He then went to Rochester, New York, to visit relatives and secure treatment from a noted surgeon there. The wound was now partially healed, but the doctor proceeded to enlarge it so as to remove the pieces of bone. Before this could be accomplished the doctor was prostrated by a long attack of fever. As neither physician nor patient had faith in the skill of others, the wound was healed before the former recovered. Thus it remained until August 26, 1866, the fourth anniversary of the wound, when the bullet was cut from the hip by the same physician, Dr. E. B. Moore.* In 1883 Mr. White was again forced to submit to the surgeon's knife, a stone having formed in his bladder around a fragment of bone floating there. This was removed at Rush Medical College, in Chicago, and he is now [1884] enjoying better health than ever before since his injury.

*The physician referred to above probably was Dr. Edward Mott Moore (1814-1902). He was the most famous surgeon in Rochester, New York, from 1840 until about 1890, and was professor of surgery in several Eastern colleges as well as in the old Starling Medical College of Columbus, Ohio. In 1890 he was elected to the presidency of the American Medical Association, and he had already served as president of the Medical Society of the State of New York.

This apparently was an instance in which a settler of Dodge County forsook the practitioners of his own community for those of the East (or at least, Chicago). The patient had settled in Kasson in 1866.

Dr. Reuben Willson (1822-1900) was a veteran of the War of the Rebellion who came to Mantorville in 1866, where he remained for about ten years.

Dr. James McLaughlin (1816-1883), a North of Ireland man, came to Mantorville in 1866 from Beaver Dam, Wisconsin. He was wealthy, affable and highly educated,[1] so that although he had practically retired from the practice of medicine by the time he came to Dodge County, he was much sought by other physicians in the county for consultation.[1]

A **Doctor Dearborn**, a woman physician, apparently was practicing medicine in Wasioja in 1866. It has been recorded,[28] for instance, that "Dr. Dearborn of Wasioja" assisted **Dr. William Worrell Mayo** (1819-1911) of Rochester at an operation for ovarian tumor in August of 1866, but little more is known about her. Woods,[13] who was able to remember her, said she was a large, determined woman who always carried a pistol, and added that "She did not last long." It would be difficult, of course, on the basis of the slight evidence available, to say that she was a Doctor of Medicine, although it certainly would not have been impossible for her to obtain such a degree in the sixties.

Next to the War of the Rebellion, the one great event of the sixties which affected the life of everyone in the state was the coming of the railroads to Minnesota.* No one was free from the effects of this tremendous development. As Folwell[29] wrote:

> As the railroad lines extended, the prairie schooner, the stagecoach, and the steamboat lost importance. The steam cars ran every day and their arrivals and deliveries were punctual. Journeys of days were shortened to hours. Grain and dairy products, which previously could stand but fifty or sixty miles of transportation to primary markets, could now be hauled hundreds of miles, and heavy commodities like coal and lumber could be shipped out in return. The movement of merchandise and mails was greatly expedited . . . The old river counties and those next behind them received goodly additions and population now flowed past them into the "back counties."

Dodge County at this particular time was a "back county," and the physician in Dodge County was affected no less than his fellow settlers by the coming of the railroads. For him the significance of the railroad was twofold: it provided him with a speedy and comfortable means of obtaining skilled assistance in times of dire need from those physicians and surgeons in Saint Paul and Minneapolis who were beginning to specialize, but it also permitted his wealthier patients to seek the professional services of well-known practitioners in far-distant metropolitan centers, as in the case of the Kasson man, previously mentioned herein, who went to the Rush Medical College of Chicago in 1883 for a surgical operation. If the railroad enabled the country physician to journey to Eastern cities at his leisure to acquaint himself with new techniques and additions to medical and surgical knowledge, it also enabled Eastern physicians or those relatively nearer to penetrate to the rural physician's village periodically, there to remain for a short while and collect respectable fees which otherwise would have gone into the pocket of the resident physician. The railroad enormously

*Undoubtedly, the Sioux Indian outbreak of 1862 aroused much consternation and alarm in Dodge County, and it is known that men from the county went to the assistance of the beleaguered settlers in Western Minnesota. It is also true that the Legislature in February of 1860 had memorialized Congress to protect settlers on the frontier "from the aggressions of the Sioux Indians" by the erection and investiture of a fort thirty miles west of the junction of the Pembina and Red Rivers, and by the re-occupation of Fort Abercrombie, built in 1858 and shortly thereafter abandoned, at Graham's Point. But the territory in which these points were situated was far distant from that in which the uprising of 1862 occurred. See: General Laws of the State of Minnesota, etc., etc., Faribault, Orville Brown, State Printer, 1860, pp. 304-305 and 310-311.

simplified the problem of the young medical graduate who wished to try out a location, even as it simplified one of the problems of the established practitioner by bringing him drugs, instruments and other supplies from the East, much more rapidly than he had ever dreamed possible.

Kasson in Dodge County is an example of a town built by a railroad; in this case, the Winona and Saint Peter Railway Company (now the Chicago and Northwestern Railway Company), in 1865 and 1866. The first passenger train reached Kasson in November of 1865.[17] The town of Kasson itself was laid out by and named for Jabez Hyde Kasson (1820-1891), a Pennsylvanian who had come to Dodge County in 1856.[17]

"Two years ago," the *Dodge County Republican*[30] of Kasson exulted in its second issue, "the site of this village was a beautiful spot of wild prairie, in a sparsely settled region. It now contains a population of nearly 400 and is rapidly increasing in size, wealth and importance."

One week later the same newspaper declared that Kasson presented a good opening for a competent physician, and in the next issue it was observed that a Doctor Willson from the East proposed to settle in Kasson.[31] On September 7 of that year (1867) the professional card of this physician appeared in the same newspaper. He was **Dr. John B. Willson,** an older brother of Dr. Reuben Willson. He was a graduate of the old Castleton Medical College* of Castleton, Vermont, and is believed to have been an aged man by the time he reached Kasson in 1867. He left Kasson in the summer of 1874. It is believed that he went to California, and that he did not resume the practice of medicine. He was known as an able, well-educated and experienced physician.

As the Winona and Saint Peter Railway Company built the town of Claremont, so also did it obliterate the hamlet of Rice Lake, on the north shore of the small lake of the same name in Dodge County. The settlement had been platted in 1856, and it had a post office, blacksmith shop, church and a few stores and houses. It was in this village that the veteran eclectic physician, Dr. Edward P. Kermott (1825-1872), practiced for a while in the fifties, as previously stated.

It was recorded that Doctor Kermott was in Rice Lake in 1857. Nine years later the Winona and Saint Peter Railway Company crossed Dodge County from east to west, and a railway station was erected at a point some five miles south of the village of Rice Lake. The population of Rice Lake naturally shifted to the site of the new railway station, which became the village of Claremont, incorporated in 1878.[17] Today only a church marks the original townsite of Rice Lake.

Wasioja was another town in Dodge County which was ruined by the railroads. At one time peopled by no less than 1,000 souls, Wasioja for years had hoped that the Winona and Saint Peter Railway Company would connect with the village in the sixties, but this did not come to pass. Hopes again were high in the seventies. "If the Dubuque & St. Paul railroad passes through Wasioja, as the citizens of the town fondly hope," it was written,[5] "it will form a junction with the Winona & St. Peter road at this point [Dodge Center]." These hopes likewise were dashed to earth.

Hence, Wasioja, which had been platted in 1856, which had opened in 1860 the Minnesota Seminary, a Free Will Baptist institution of learning known throughout the entire state, and which was recognized far beyond the county for its famous "Wasioja stone" quarries, declined rapidly. Today it is scarcely

*For an interesting account of this old medical school see: Waite, F. C.: Birth of the First Independent Proprietary Medical School in New England, at Castleton, Vermont. Ann. Med. Hist. 5 (n.s.): 242-252, (May) 1925.

more than a "ghost town," brooding in sepulchral stillness over its once sanguine destiny.

Other towns in Dodge County were similarly affected by the railroads. It was written:[32]

> The rapidity with which some of these station villages grew was often marvelous and always very agreeable to lucky proprietors. The order in which there rose about the railroad "depot" the elevator, the store, the blacksmith shop, the saloon, the school, the church, and the post office became almost stereotyped. In a single season all these would sometimes appear. The development of these railroad towns was disastrous to many older villages, platted at what seemed to be points of vantage. In some cases, when these were not too far from new towns at the railroad stations, they were literally put on wheels and moved thither. Some well-built towns farther away . . . were gradually deserted and their buildings afterwards actually rotted down.

There was by this time a respectable number of physicians in Dodge County. Some were superior physicians who could have maintained a fine practice anywhere, city or rural region. It would be logical to suppose that some sort of medical organization would be formed within the county, but the first society of which the authors have record was not founded until 1869.[33] It will be considered in more detail later.

The first railway train to reach the new town of Dodge Center arrived at that place on July 13, 1866.[17] In the late spring or summer of 1867 **Dr. D. L. Tyler**, who had been living in Ashland, opened a general store at the new railway town,[5] where he became postmaster in the same year. It was reported[34] in the summer of 1868 that "Dr. Tyler is doing a fair small trade in notions. He wears his honors as postmaster with dignity." In 1871 it was said that he was engaged in the manufacture of the "German Rat, Mouse and Insect exterminator."[35] It should be pointed out that an old resident of Dodge Center, Dennis Lynch,[36] said he remembered Tyler well, but did not recall that he ever practiced medicine, and did not believe that Tyler was a regularly graduated physician.

A history[5] of Dodge County printed in 1870 contained a full-page advertisement of Tyler's store, which was represented as being situated at Dodge Center. An excerpt from this advertisement follows:

> D. L. TYLER
> General Dealer in
> DRY GOODS
> and
> GROCERIES
>
> Boots and Shoes, Hats and Caps, Yankee Notions, Drugs and Medicines, Crockery and Glassware, Toilet Articles, Perfumery, &c.

This man apparently was the Dr. D. L. Tyler mentioned above. He seems to have been an earnest merchant, for he informed his readers that:

> My shelves are always filled with a GENERAL ASSORTMENT of all things Useful and Ornamental, and, like the accommodating Yankee, if I have not got what you want I will get it. I am bound to supply my customers with what they want
>
> AT CHEAP RATES!
> DODGE CENTER - - - MINN.

The subsequent history of this man is not known, but he was still living in

1885.* Lynch[36] believed he went to Dundas, Minnesota, and that he there opened a general store. It has not been possible to trace his relationship to medical practice in Dodge County, and the authors are not able to say whether or not he was a Doctor of Medicine.

The year 1868 in Dodge County seems to have been a tranquil prelude to the gale that was to break only a few years later. The summer was reported as being salubrious; Dr. John B. Willson of Kasson had so few patients that he amused himself by gardening. In September the *Dodge County Republican* of Kasson was replete with advertisements of Wahoo Bitters, Indian Saguwa, Indian Root Pills, Hoffland's German Bitters, Coe's Cough Cure and Coe's Cough Balsam, as well as the Galenic Medical Institute of Saint Paul, of which Armstrong[37] has written.

At some time in 1868 **Dr. Charles Severin Beaulieu** (1835-1896) settled in Concord. He seems to have been a curiously erudite man who could practice medicine or occupy a pulpit with equal facility. Doctor Beaulieu came to Dodge County from Indianapolis, where he had practiced medicine since his discharge from the Union armies in either 1863 or 1867. He remained in Concord until November of 1880, at which time he responded to a call which took him to Brownsdale in Mower County as pastor of the Christian Church there.

The name of **Dr. Charles Lee,** an eclectic physician, stimulates what must remain conjecture, for the details of his rather turbulent career are not clear. He was married to Emma Higbe (1847-1874) of Concord Township on September 30, 1867, and at that time he was said to have been a young man. In February of 1868 it was announced in the *Dodge County Republican* of Kasson that Doctor Lee would be at his "old office" on Main Street in Kasson on Saturdays, a statement that would imply that he had practiced in Kasson before that year. An "A. H. Lee, M.D.," was listed in a directory of Wasioja, contained in a history[5] of Dodge County that was issued in 1870, and this no doubt was Dr. Charles Lee, for there was no other physician with this surname in the county at the time. In a work[38] issued in 1937 it was said that Doctor Lee was the only physician in Claremont for the first five years of that town's existence, but that during part of this time he lived at Wasioja. He is known to have been living in Claremont with his wife in 1869. It was in 1869 that he was elected treasurer of the Minnesota State Eclectic Medical Society, founded at Owatonna on May 26, 1869.[39] An old resident of Claremont declared that as a boy he had suffered a fractured leg, for treatment of which Doctor Lee was called from Owatonna, where he was supposed to have been living at the time.

In its issue of January 28, 1870, the *Dodge County Republican* of Kasson printed a business directory of the town of Dodge Center. In this directory Dr. Charles Lee was listed as the only physician in Dodge Center.

The only Charles Lee licensed to practice medicine in Minnesota was **Dr. Charles Edward Lee** (1842-1918), who was graduated from the Medical Department of Columbia College of New York City in 1866. On the basis of these dates, it would have been possible for Doctor Lee to be in Wasioja in 1867, as noted above. This Doctor Lee was licensed to practice medicine in Minnesota on October 11, 1883;[40] he practiced in various towns in Minnesota before he moved to Saint Paul, where in 1890 he attended **Dr. P. Sprague Haskell** (1832-1890) of that city during his last illness. Doctor Haskell died in Saint Paul on September 26, 1890.

*He visited Kasson on April 23, 1885. The *Dodge County Republican* of Kasson in its issue of April 30, 1885, observed: "D. L. Tyler, Esq., the first postmaster and merchant of Dodge Center, visited Kasson on Thursday last, for the first time in twelve years. We acknowledge a call."

Dr. Charles Edward Lee became a member of the Minnesota State Medical Association in 1903, and at the time was still living in Saint Paul. He died suddenly in his office in Los Angeles, California, on April 23, 1918.[41] It seems likely that he was the Doctor Lee who was in Dodge County in the sixties, although this is not certain.

In September of 1869 the Dodge County Medical Society was founded.[33] This society may have been only intermittently functional, but it nevertheless endured until 1934, as will be set forth later.

(To be continued in April issue)

ARMY'S 1943 RECRUITING PROGRAM WILL REQUIRE 6,900 PHYSICIANS

The 1943 recruiting program of the Surgeon General of the Army calls for the commissioning of 6,900 physicians and approximately 3,000 hospital interns and residents, it is reported in *The Journal of the American Medical Association* for March 13 in an outline of the new procedure of processing physicians, dentists and veterinarians for the Army. The program also calls for the commissioning of 4,800 dentists and 800 veterinarians.

Physicians will be procured from the following twenty states and the District of Columbia: California, Colorado, Connecticut, Illinois, Iowa, Maryland, Massachusetts, Minnesota, Missouri, Nebraska, Nevada, New Hampshire, New Jersey, New York, Ohio, Oregon, Pennsylvania, Rhode Island, Vermont and Wisconsin.

The following states have already contributed more physicians to the armed forces than the sum of their 1942 and 1943 quotas and will not be called on to furnish any more physicians, except interns and residents and except special cases for specific position vacancies, during 1943: Alabama, Arizona, Delaware, Georgia, Idaho, Kentucky, Louisiana, Mississippi, New Mexico, North Carolina, South Carolina, Tennessee, Texas, West Virginia and Wyoming.

It is stated that at present there will be no procurement of physicians, except interns and residents and in special cases for specific position vacancies, in those states not listed above. There will be no procurement of dentists, except special cases for specific position vacancies in the following sixteen states: Alabama, Arizona, Arkansas, Delaware, Florida, Georgia, Kentucky, Louisiana, Mississippi, New Mexico, North Carolina, Oklahoma, South Carolina, Tennessee, Texas and Virginia.

At the present time there are no restrictions on the recruiting of veterinarians.

In the instructions issued by the Army it is pointed out that the Surgeon General has discontinued all medical officer recruiting boards and that under the new procurement program no physician, dentist or veterinarian will be commissioned in the armed forces of the United States until he has been declared "available" by the Procurement and Assignment Service of the War Manpower Commission.

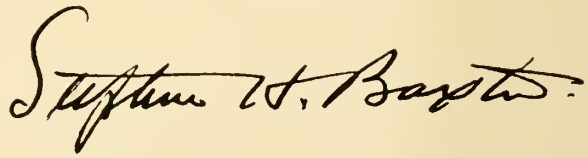
In each state the Procurement and Assignment Service has set up three state chairmen: medical, dental and veterinary. Each of these prepares a monthly quota list of physicians, dentists and veterinarians who are apparently suitable and who are available, for commissioning in the Army of the United States. This list is submitted to the central office of the Procurement and Assignment Service which sends a communication inviting such individuals to apply for service with the armed forces. On the reply card enclosed with the invitation the individual states his preference for the Army, Navy or Medical Department of the Air Forces. These reply cards are sent by the potential applicants to the state chairmen of the Procurement and Assignment Service who in turn submit lists of such potential applicants to the Officer Procurement Service of the Army.

On receipt of such lists the officer procurement district office contacts the potential applicant and arranges for an interview regarding a commission.

Applicants will be requested by the officer procurement district office to complete all papers and take all steps required of them within fourteen days of the date of such request. If this is not complied with, a report thereon will be transmitted by the officer procurement district office to the state chairman of the Procurement and Assignment Service.

The decision as to the grade and appointment to be recommended for each candidate rests with the Surgeon General, not with the Officer Procurement Service.

President's Letter



MODERN three-dimensional warfare has made obsolete the old conceptions of warfare with a front line of combat, a more or less inactive intermediate zone and, far to the rear, areas in which the devastation of war is not directly felt. Any part of a nation at war may now become at any time an area of actual combat. The medical profession fully realizes this possibility, and for that reason, it is in no mood of "business as usual" that our Association meets this year in its 90th annual convention.

The importance of the "home front," under these conditions, is recognized not only by civil, but by military authorities, and special dispensations are made for physicians caring for the civilian population. Many conventions of national scope have been discontinued for the duration, but the holding of local and state medical meetings is not only approved but encouraged.

It is the privilege and the duty of the members of our Association, as many as can possibly do so, to attend the convention. There is an enthusiasm in numbers, a "summation of stimuli" which varies in direct proportion to the number of persons present. This is your meeting. The Program Committee, the officers of the Association and the committees of the Hennepin County Medical Society are united in the effort to make it interesting, stimulating, refreshing. It presents attractions and features which, in the language of a well-known document, are "yours to enjoy, yours to preserve, yours to transmit" to your neighbors who unfortunately cannot be present.

In the week following the convention a Course in Radiology is offered at the famous Continuation Center at the University of Minnesota. Here a physician enrolled in the course may live at nominal cost in a building built and equipped in a manner that compares favorably with an exclusive private club, and he may pursue his studies under the most pleasant and stimulating conditions.

It is none too soon now to lay plans for taking advantage of one or both of these opportunities. Prepare to contribute something to the meeting of your Association, if only your presence and enthusiastic interest. Your own mental stimulation and the contribution it will make to the maintenance of morale on the "home front" will amply justify such a meeting even in time of war.

President, Minnesota State Medical Association

PNEUMONIA TODAY

While pneumonia in Minnesota never had the high mortality that was experienced in the Eastern states, yet, until recently, it was one of the major causes of death. Not so long ago patients suffering from this disease were placed outdoors, even in zero Minnesota weather, with the mistaken idea that "fresh air" was good treatment even though cold. It eventually was realized that cold air is irritating to an inflamed respiratory tract, and fresh but not cold air is indicated. Nursing and a sedative constituted the essential treatment.

Pneumonia serum for pneumococcic forms of pneumonia constituted a great advance in the therapy of the disease and reduced the mortality at least 10 per cent. The serum, of course, was ineffective for the bronchial types of pneumonia complicating influenzas, measles, whooping cough and respiratory infections. Then came the sulfa drugs which proved themselves highly effective in pneumococcic pneumonia and have replaced serum therapy. Perhaps we were unduly optimistic in thinking that the sulfa drugs would be as effective in that group of pneumonias not caused by the pneumococci. It has come to be recognized that they are not effective in a large group of pneumonias the causes of which we do not know.

In this issue we are publishing an article on "Atypical Pneumonia" by Dr. Wesley W. Spink who has interested himself in the subject of pneumonia and also in that of the sulfa drugs. He emphasizes the fact that the organism which is the etiological factor in many cases of pneumonia is unknown and cannot be determined even with the aid of a first-class laboratory. Many are atypical and lack the textbook physical findings.

A real value of Dr. Spink's article to the practitioner is the point that sulfadiazine or sulfathiazole should be given at the onset of an acute infection suggesting pneumonia, but if after forty-eight hours there is no improvement in the symptoms it should be discontinued, for one is probably dealing with a pneumonia unaffected by the drugs and further administration is likely to confuse the picture and do more harm than good. The same may be said for the prolonged use of these valuable drugs for other infections and the profession should be alive to this danger.

THE ORR TREATMENT OF COMPOUND FRACTURES

While Dr. H. Winnett Orr of Lincoln, Nebraska, may not have been the originator of the closed cast treatment of compound fractures, he was responsible for proving its value and the method is one of the few progressive steps which can be placed on the credit side of World War I, medically speaking.

His method consists, briefly, in cleansing a compound fracture with soap and water, shaving the skin and treating it, but not the wound, with a weak tincture of iodine, debridement, the application of vaseline gauze and a closed plaster-of-Paris cast. Infection is given secondary consideration to absolute rest of the injured parts.

The profession has been admittedly slow in adopting this revolutionary method in the treatment of these wounds which in most cases are infected. Many a surgeon has felt that he would be laying himself open to a suit for malpractice if he used the treatment. Nevertheless, the method has been generally adopted by the military forces and was used to advantage at Pearl Harbor.

In the March number of *Harper's* appeared an article by Leigh White entitled, "Dr. Orr Packs Them in Plaster." While in Greece Mr. White sustained a severe compound fracture of the femur and ten days elapsed before he received any surgical care. He feels he was poorly treated for many months until he sought the services of Dr. Orr in Lincoln. His article relates the story of the Orr treatment and Dr. Orr's difficulties in having his method generally recognized.

The profession, as a rule, has been conservative in the adoption of new ideas in medicine. We were very slow in accepting Pasteur's discovery of

the part played in disease by micro-organisms, Jenner's discovery of vaccination against smallpox, Reginald Fitz's conception of appendicitis, Herrick's description of coronary thrombosis. New ideas which represent medical progress, however, are eventually recognized.

A certain amount of conservatism is a professional asset. Many new ideas and methods do not stand the test of time. Among many such proposals are: twilight sleep, Potter version, thymus extract and various serums recommended for carcinoma, dinitrophenol for reducing weight, intensive chemotherapy for syphilis and staphylectomy for the prevention of the common cold. Other therapeutic measures which have some value but must be used with care are gold salts in arthritis and pituitrin in obstetrics. We are not at all sure but what continuous caudal anesthesia in obstetrics should be placed in this latter group. The added expense incident to this procedure and possibly an increased hazard may prove it inapplicable for general use.

New and untried medical procedures should be presented first to the profession for consideration and trial. Articles on new and unproven medical procedures have no place in newspapers and lay periodicals. This applies to the *Harper's* article on the Orr treatment of compound fractures. The article gives the impression that the profession at large is unprogressive and not receptive to new ideas. Recent medical progress refutes the implication.

AMA LEGISLATIVE ACTIVITY

IT is hoped that every one of our members will read the article entitled "The Doctor of Medicine and His Responsibility" by Dr. Alfred W. Adson of Rochester, which appears in this issue of MINNESOTA MEDICINE. Dr. Adson brings out very clearly the need for a more active part in national and state legislation in matters pertaining to medicine and public health. Anyone who has followed the trend of proposed legislation in Congress by other than medically minded individuals can realize that advice from the medical profession is sorely lacking. This is a responsibility which rests on the medical profession of the country.

Many state medical organizations, our state medical association for one, have seen the need and have accepted the responsibility of advising state legislators in medical matters, to the bene of public health and public economy. The ne for an active policy on the part of medical men informing the public regarding medical matte has been appreciated for some years. The AM has been active in publicizing the science of me icine and the publication *Hygeia* is an example such activity. To add to this activity the Nation Physicians Committee was formed and has do extensive and valuable publicity work. There a growing feeling that mere publicity is n enough; that our national association should active in Washington just as our state associ tions are active in state capitols.

As Dr. Adson says, the statement of Justi Miller of the United States Court of Appea that it was perhaps the failure of professiona groups to guide legislation which was responsib for the untoward outcome in the case of th United States of America versus the America Medical Association, constitutes a direct challeng to the physicians of the country to take an inte ligent, helpful and fair stand in the enactmer of legislation that concerns the public welfar and the welfare of medicine itself. This wa pointed out some time ago by the National Phy sicians Committee. The question is now raise whether representatives of the AMA with th prestige of the national association behind then and assigned to Washington are not the logica ones to accept this challenge.

It should be explained that two reasons hav been advanced why the AMA has been ham strung in meeting the need for adequate represen tation in Washington. The first explanation give is that the constitution and by-laws of the AM would not permit it, and the second justificatio given is that to do so would subject the AMA t a Federal income tax. To us there is no merit i either one of these positions. In the first plac Article II of the Constitution of the AMA pro vides: "The objects of the Association are t promote the science and art of medicine and th betterment of public health." We know of n sounder way of promoting "the science and ar of medicine and the betterment of public health" than to make available to national and state law-making bodies and to others, scientific data and sound medical opinion in reference to such matters.

With respect to the liability for income tax we are advised that the exemption contains the fol-

wing restriction: "Provided no substantial part the activities of which is carrying on propanda, or otherwise attempting, to influence legslation." Such an absurd restriction should ever have been passed in the first place, and we oubt that it would have passed had the various roups, including the AMA, who are concerned ith this matter, been on the job in Washington. owever, we are far from convinced that any ch activities, even though entered into, would onstitute a "substantial part of the activities" of e AMA. A careful reading of the exemption ction of the United States Internal Revenue aw fails to disclose any such restriction being ttached to labor unions, agricultural groups, raternal beneficiary societies, building and loan ssociations, business leagues, chambers of comerce, real estate boards, civic leagues and nuerous others. Apparently these groups were ell represented in Washington when such legisation was being drafted.

This law should be changed and if organizaons like the AMA are prevented from accomlishing this proper object, such an organization s a National Physicians Committee might well ttempt it.

ALFRED BLALOCK

DURING the second week in March, Dr. Alfred Blalock, Professor of Surgery and Director of the Department of Surgery of Johns Hopkins Medical School, spent three days on the campus of the University of Minnesota as the guest of the Medical School. On Thursday evening, March 11, 1943, Dr. Blalock gave the tenth E. Starr Judd Lecture in the Museum of Natural History Auditorium. The subject of Dr. Blalock's address was "Traumatic Shock with Particular reference to War Injuries."

During his stay, Dr. Blalock participated also in the postgraduate week in Surgery conducted under the auspices of Dr. William A. O'Brien, Director of Postgraduate Medical Training in the Continuation Study Center. Dr. Blalock held two Surgical Colloquia before the group of sixty-four physicians and surgeons who attended the postgraduate week in Surgery, discussing primarily: burns, myasthenia gravis and surgical diseases of the thorax, including bronchiectasis, adenoma of the bronchus, lung abscess, constricting pericarditis and patent ductus arteriosus. Dr. Blalock gave a lecture also on "Surgical Diseases of the Heart," reviewing his own extensive experience with these disorders. On Friday, March 12, Dr. Blalock participated in a two-hour seminar discussion with members of the faculty on "Problems of the Circulation," in which special consideration was given to shock and hypertension.

Everyone who had the opportunity to hear Dr. Blalock, including members of the postgraduate group, students and faculty alike, was most enthusiastic in praise of his presentations. Dr. Blalock is probably the keenest exponent of the experimental or physiological approach to clinical surgery in America. Dr. Blalock's visit to the Medical School will be long remembered, not alone for the critical character of his lectures and discussions; his innate modesty and winsome manner have gained for him an additional large number of ardent admirers.

These ten years of lecturers sponsored by the E. Starr Judd Lectureship in Surgery have brought to the Medical School some of the best surgical talent in America. Dr. Judd's benefaction has made an indelible impress for the better upon this medical community. The remembrance of so distinguished a son of Minnesota is a stirring stimulus to us all. Dr. Blalock's visit affords us again the occasion to cherish Dr. Judd's memory with pride, affection and gratitude.

BUY WAR BONDS

THIS month our government is putting on a drive to float several billion dollars worth of bonds. Banks and corporations are being given the opportunity to invest spare funds in these bonds. Individuals are being urged to do what they can in putting their spare dollars to work for Uncle Sam.

An amateur economist during World War I wrote in a prominent magazine to the effect that each generation pays the cost of its war. This was news to many and its fallacy will beccome evident from the taxation which will be required to pay interest on our national debt following the present war.

The cost of the present war will have to be paid somehow. Only a part of the billions required can be met by taxes—the remainder will have to be furnished by loans to the government in the form of bonds. Economy, wherever possible on the part of government and citizens, is of vital importance. Savings can find no better investment than in government bonds, not from a standpoint of immediate monetary return, but

quite possibly from a monetary standpoint in the future, for what would any investment be worth after the war if we do not win?

From the standpoint of personal selfishness, as well as patriotism, *buy war bonds.*

PHYSICIANS MUST VOLUNTEER FROM LARGER CITIES

Young available physicians in the large cities of the country, particularly in those of the eastern seaboard, whose failure to volunteer has caused a lag in the procurement of medical officers for the armed forces, should be called before the bar of public opinion, *The Journal of the American Medical Association* for March 27 declares in an editorial. *The Journal* says:

"At a recent meeting in Washington of the Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians with the Officer Procurement Service of the United States Army and with representatives of other governmental agencies, evidence was clearly set forth that the procurement of medical officers for the armed forces is lagging. The responsibility rests unquestionably on the failure of young available physicians in the large cities of the country, particularly those of the eastern seaboard, to volunteer. Officers of the medical societies of New York, Massachusetts and Connecticut were present and the situation was placed before them. The rural areas of the United States have contributed doctors not only up to such quotas as were assigned to them but in many instances well beyond these quotas; it is simply impossible to anticipate that they will make a further contribution at this time. In the meantime, New York, Brooklyn, Boston and some of the larger communities in the states of Connecticut, New Jersey, Pennsylvania and California have failed even to approximate their quotas.

"The needs of armed forces for physicians during 1943 are well defined. The number of physicians to be expected from recent graduates, interns and those now holding residences has been determined. Beyond this number at least six thousand more physicians must come from the civilian population. The Procurement and Assignment Service for Physicians, Dentists and Veterinarians has devised a technique which involves, first, a determination of the availability of the physician concerned or his essentiality for any civilian position which he occupies; second, notification of the physician of his availability and a request that he appear before his local procurement board; third, a notification of the Selective Service Board of the fact that the physician concerned is considered available and that he has failed to volunteer. Thus far pressure beyond this has not been exercised. There remains, however, the mobilization of the pressure of public opinion.

"In some instances physicians have declared flatly to representatives of the Procurement and Assignment Service and the Officer Procurement Service that they do not wish to volunteer and that they will not volunteer. When it is known to other physicians in the community that a physician under thirty-eight years of age, declared available by the Procurement and Assignment Service, refuses to volunteer in this time of the nation's need, when many an older physician, frequently with innumerable obligations, has given up his home, his practice and the responsibilities of years to participate in this war, the public has a right to know that the younger physician is not willing to do his part. Certainly the Procurement and Assignment Service should consider the possibility at this advanced stage of the war effort of making public through the state medical journals not only the names of those who are already participating in the war but also the names of those who have been declared available and have not themselves ever indicated a willingness to participate. Let them be called before the bar of public opinion!"

CLINICAL PATHOLOGICAL CONFERENCE

(Continued from Page 372)

mated to weigh 800 grams. There is extensive fibrosis and slight calcification of both the mitral and the aortic valves so that they admit only a finger tip. In addition, there is an irregular soft vegetation 4 mm. in diameter on the posterior mitral leaflet. The tricuspid ring is dilated, measuring 15 cm. in circumference. Both ventricles are hypertrophied and all the chambers are somewhat dilated, especially the left auricle.

Two centimeters beyond the orifice of the left subclavian artery there is a thin septum across the aorta which has an opening 7 mm. in diameter in its center. The diameter of the aorta is moderately reduced in this region for about 3 cm. There is no evidence of the ductus arteriosus.

The only findings in the abdomen were two fresh red infarcts in the spleen; the spleen weighed 190 grams.

A smear was made from the vegetation on the mitral valve and it showed gram positive cocci.

DR. HERTZOG: As you can see, the internal mammary arteries are greatly dilated. They arise from the subclavian arteries, which are proximal to the constriction, and astamose with the anterior branches of the intercostal arteries. An efficient collateral circulation develops. The tortuous intercostal arteries produce a peculiar notching of the lower borders of the ribs which often can be seen on x-ray films of the chest. In this case these x-ray findings in the ribs were minimal and were considered to be within normal limits.

DR. PEPPARD: I think that one should palpate the femoral arteries when examining patients with heart disease. If that had been done, one probably would have noticed diminished femoral pulsation. That would have been a clue to the recognition of coarctation of the aorta. Then further, examination probably would have shown reduced blood pressure in the legs as compared to the arms, and possibly pulsating intercostal arteries.

INTERN: Is it unusual to live as long as he did with coarctation of the aorta?

DR. PEPPARD: No. Some cases live even longer. However, many die in infancy and about 50 per cent die during early adult life.

DR. LOFSNESS: The pathogenesis of coarctation of the aorta appears to be related in some way to closure of the ductus arteriosus. The root of the aorta usually dilates proximal to the constriction; often an aneurism forms and quite a few die from rupture of this aneurism. Many of them die of congestive heart failure. Some of the older patients die of cerebral hemorrhage because of the hypertension. The primary cause of death in this case was lobar pneumonia. The old rheumatic valve defects, the adherent pericardium and the coarctation of the aorta apparently played only a minor role in his death as there was no evidence of heart failure. The bacterial endocarditis appears to have been a terminal process.

Anatomical Diagnosis: (1) Lobar pneumonia; (2) old valve defects (aortic and mitral); (3) acute bacterial endocarditis (mitral); (4) adherent pericardium; (5) coarctation of the aorta.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics

George Earl, M.D., Chairman

THE PLANNING BOARD REPORT

Congressional reaction toward the report of he National Resources Planning Board is said have been lukewarm. While editors have een exploring America's five-pound (by weight) lue print for postwar living, Congressional com- ittees have continued to refuse appropriations or perpetuation of the board which created it.

Many bills for extension of the present Social ecurity Act into new fields have been referred o committees, but few, so far, have come out f them with recommendations for passage.

Congress for Delay

The prevailing temper of Congress seems to e to delay any further sweeping social legisla- ion until the war is out of the way. The attitude f the President and the planners, on the other and, is that action to prevent terrible economic islocation and wide-scale suffering after the war nust be taken now.

What will eventually happen in America de- ends upon many factors still hidden in the ncertainties ahead.

The general trend all over the world has been o protect common men from the hazards of life nd it is highly improbable, even in the face of ostwar reaction, that America will fail to move considerable distance in that direction.

Some highlights of the Planning Board report levoted to the public social services are quoted elow:

"Public services essential to the health, education nd welfare of the population should be available hroughout the country, especially in areas which are isadvantaged in respect to income and taxable wealth.

"In most communities, marked expansion of present ervices will be required in order to achieve these bjectives. The planning and administration of public ocial services should be lodged in appropriate agencies f government and responsibility for their development hould be shared by local, state and federal authorities.

"For More Adequate Medical Care"

*"It is essential that public provision be made for meeting the needs of our people for more adequate medical care.** Toward this end, the federal government should stimulate, assist or undertake constructive action to provide such care for the millions of our people whose need cannot be fully met from their own resources. Such a program should include adequate provision for promoting the health of mothers and children.

"State and local child-welfare services for the prevention of child neglect and delinquency and for promoting adequate care of children requiring special attention should be expanded with the assistance of the federal government so as to be everywhere available.

"Free school lunches should be provided for all school children.

"The bulk distribution of surplus commodities should be replaced by the stamp plan and greater efforts should be made to prevent the availability of commodities from concealing the inadequacies of general public assistance or from leading to a reversion to payments in kind.

Aid for the Low-income Population

*"Surplus commodities should be available to the entire low-income population, not merely to public-aid recipients."**

The final statement, above, reflects the tenor of the entire document. It is obvious that not merely surplus commodities but essential services are to be made available on some basis, presumably without cost, to "the entire low-income population."

Those who look to the new Congress to hold in check a trend toward great and immediate expansions of Social Security aids must also remember that we are traveling a road down which England has preceded us. The conservative Churchill has lent enthusiastic support to the principles embodied in the Beveridge report and America has never failed, thus far, to follow the leadership of England in domestic and social legislation.

*Italics are ours.

Physicians Must Shape

For physicians, the problem is not, how shall we stop the trend, but, how shall we shape it to protect our own preëminence in education, standards of practice and in personal responsibility? Shaping our own pattern will certainly require more than criticism from the sidelines. It will require close contact with all agencies and organizations on the Washington front and active direction of all policies related to medicine and the public health before they are crystallized into law and regulation.

THE COUNCIL MEETS

Complications involved in the current system of payments to state and county institutions for care of tuberculous patients from so-called unorganized counties were the subject of extensive discussion at the February meeting of the Council.

Sanatorium Costs and Payments

The per diem cost to unorganized counties (in which there are no county-supported institutions) of patients sent to the state institution at Ah-Gwah-Ching is only $1.40 while per diem costs of these patients in neighboring county institutions ranges from $2.50 to $4.50. County officials are therefore reluctant to send patients to the county institutions though they may be much nearer home and even though lack of empty beds at the state sanatorium may entail long and dangerous delays.

Dr. A. T. Laird, superintendent of Nopeming Sanatorium, expressed the hope that the Council would recommend legislation at this session to rectify the situation by increasing state payments for nonresident patients at county institutions. The extra five dollars a week, authorized by the last legislature in an attempt to equalize matters, was not sufficient, he said.

Dr. E. K. Geer, medical director of Ancker Pavilion, represented the Committee on Tuberculosis in the discussion. He acknowledged the need for some equalizing legislation but submitted the opinion of his committee that the whole matter of costs and payment needs extensive study by competent state agencies before legislation is recommended. He suggested also that the problem of incorrigible patients, subject of another action by the Committee on Tuberculosis, be included in the study looking toward eventual recommendations for forcible detention in institutions.

The Council agreed and passed a resoluti recommending that a study of both problems l made by the State Board of Health and tl Division of Social Welfare, in preparation f the introduction of sound legislation on the ma ter at the next session of the legislature.

Meantime the Council also approved a su gestion by Dr. E. J. Simons, council memb and Chief of the Medical Unit of the Divisi of Social Welfare, that the division act now make temporary adjustments between state ar county institutions for the tuberculous by rai ing per diem payments required of the unorgar ized counties for patients sent from their cou ties to the state sanatorium.

Committee Dissolved

Résumé of the brief career of the Committ to Study Medical Services which was organize last fall at the request of the Minnesota Sta Conference on Social Work was given to tl Council by Dr. George Earl of Saint Paul.

This committee, designed at its inception a a conference committee, was expanded to inclu equal representation from all of the organiz tions engaged in medicine and public healt work as a result of action inspired by physician hospital executives, public health officials ar dentists of the state, all of whom rightly co sidered that their associations might have som thing substantial to offer such a study.

At its first meeting, this representative grou found itself baffled by the magnitude of the ta and a total lack of funds. At the second meetir the field of study was narrowed to include on medical services in the state for the indige and each organization was requested to pr vide any available studies or summaries on th subject for consideration of the committee. Th Minnesota State Medical Association, through i representatives, Dr. Earl, Dr. W. A. Coventry Duluth and Dr. A. W. Adson of Rochester, du presented a careful summary of the evolutic of medical services for the indigent in Minn sota, noting its weak points and making recon mendations for improvement. No other organ zation presented any data whatever and at tl third and final meeting of the committee th majority of the members came to the concl sion that it was medical services to low-incom groups which should really engage their atte tion, after all—not medical services to the i

ent. But any useful survey of the actual ent of medical services for low-income groups uld require funds. So they dissolved by mu- l agreement until such time as their respec- organizations—or somebody else—should ply them with funds.

The history of this effort might well serve as varning to other equally casual attempts to ve complicated social problems. As a matter fact, surveys of medical care have taxed the st experienced and intrepid investigators even ere they have been equipped with unlimited ids. It may be that any extra funds which ght in the future be found by the participating anizations could be put to better use.

afness Bill Approved

A bill to provide a statewide program for ction, medical correction and educational ad- tment of children with impaired hearing was sented by Dr. Horace Newhart, of Minne- lis, chairman of the Committee on Deafness evention. The Council approved it in prin- le and referred it for further action to the mmittee on Public Policy.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. DuBois, M.D., Secretary

Ex-convict and Quack Returned to Minneapolis Workhouse to Serve Balance of Sentence

: State of Minnesota vs. Frank J. Brady, alias Frank Bateman

On March 23, 1943, the Honorable Frank E. Reed, lge of the District Court of Hennepin County, made order revoking a stay of sentence previously grant- Frank J. Brady, fifty-seven years of age, and order- Brady taken to the Minneapolis Workhouse to ve ten months remaining on a sentence imposed y 7, 1941.

Brady was released from the Minneapolis Work- use September 20, 1941, after serving 2½ months of one-year sentence for practicing healing without a ic science certificate. Brady was released so that could obtain employment with the Dakota Union rminal at Fargo, North Dakota. Brady was also uired to remain out of the State of Minnesota for eriod of five years. This condition was violated by ady when he returned to the City of Minneapolis l his presence was reported to the Minnesota State ard of Medical Examiners on March 20, 1943. rough the coöperation of Mr. Michael J. Dillon, unty Attorney of Hennepin County, the Minneapolis lice Department and Sheriff Earle Brown, Brady s immediately arrested and lodged in the Hennepin unty Jail. Three days later he was ordered returned the Minneapolis Workhouse by Judge Reed and ll now have to serve his entire sentence.

Brady has a long criminal record dating back to 1922 when he pleaded guilty in the District Court of Ramsey County to an information charging him with grand larceny in the second degree. In October, 1931, he pleaded guilty in the District Court of Hennepin County to the crime of manslaughter in the first degree, following the death of a woman from a criminal abortion. Brady served thirty-one months for the first offense and six years for the second offense. Brady's ex-wife, Isabelle Bateman, also served three years in the Women's Reformatory at Shakopee for criminal abortion.

Minneapolis Drug Addict Sentenced to Five-Year Term in the Women's Reformatory at Shakopee

Re: State of Minnesota vs. Madelyn Houchins Tremont, alias Mrs. Charles Rayburn, alias Peggy Lane, alias Marguerite Moore, alias Rose Fields, alias Madelion Field, alias Madelyn Frances.

On March 22, 1943, Madelyn Houchins Tremont, thirty-four years of age, was sentenced by the Honorable Arthur W. Selover, Judge of the District Court of Hennepin County, to a term of not to exceed five years in the Women's Reformatory at Shakopee. The defendant had pleaded guilty on February 9, 1943, to an information charging her with obtaining narcotic drugs by fraud, deceit and subterfuge. The defendant at the time of her arrest resided at 610 Adams Street, N.E., Minneapolis.

This defendant has a long criminal record of shoplifting and numerous other offenses. She admitted having been addicted to the use of narcotic drugs for the past nine years. There is evidence, however, that she has used narcotic drugs for the past sixteen years. The defendant was first arrested in 1926 at Louisville, Kentucky. Since that time she has been arrested in Michigan, Ohio, and in 1939, the defendant was arrested at Fergus Falls, Minnesota, charged with grand larceny in the second degree, growing out of the alleged theft by this defendant of a fur coat from one of the Fergus Falls stores, The coat was subsequently paid for and the defendant fined $50 and costs for petit larceny. In April, 1940, the defendant was arrested on a similar charge at St. Cloud. She paid for the coat and also made good a worthless check. On July 6, 1942, the defendant was found guilty of violating the Minneapolis City Drug Ordinance and sentenced to thirty days in the Workhouse.

The Minnesota State Board of Medical Examiners wishes to commend Judge Selover for refusing to place the defendant on probation, notwithstanding her claim of being pregnant. The defendant's record indicates, conclusively, that she will not free herself of drug addiction by any voluntary methods. It is also appalling that this defendant was able to obtain narcotic prescriptions from at least one member of the medical profession in Minneapolis with practically no difficulty whatsoever. Had the slightest effort been made by this physician the true identity of the defendant could have been ascertained at once through the Minneapolis office of the Federal Bureau of Narcotics.

In Memoriam

WILLIAM BLACK

Dr. William Black, for the past twenty-six years a practitioner at Mankato and prominent in club and fraternal organizations in that city, died February 13, 1943, at the age of sixty-five.

Dr. Black was born at Rossville, Indiana, January 13, 1878, and graduated from the Frankfort, Indiana, High School in 1898. He received his B.A. degree from Wabash College at Crawford, Indiana, in 1903 and his medical degree from the University of Minnesota in 1909.

After practicing at Parkers Prairie, Minnesota, for a year and at Tyndale, South Dakota, from 1910 to 1915 and at Gaylord, Minnesota, for two years he moved to Mankato in 1917 where he has since practiced.

Dr. Black was prominent in the Masonic Lodge, was a patron of the Eastern Star, a member of the Kiwanis Club and the Elks Lodge. He was also a member of the Blue Earth County Medical Society, the Minnesota State Medical Association and the American Medical Association. At one time he was chief of staff of the Immanuel Hospital of Mankato.

In 1910 Dr. Black married Lillian Bausman of Minneapolis. Following her death in 1938 he married Evelyn Sumner Schrupp who survives him. Also surviving are two daughters, Lt. Mary Black of the WAAC and Mrs. Dorothy LaBrie of Minneapolis and four grandchildren.

OTONIEL FLORES

Dr. Otoniel Flores of Dodge Center, Minnesota, died at Rochester, March 5, 1943, at the age of fifty-five.

Dr. Flores was born at Heridia, Costa Rica, August 24, 1887. He received his early education in Costa Rica and obtained a B.A. degree from the Liceo De Heridia in 1912. He attended the University of Pennsylvania Medical School from 1914 until 1917 and obtained his medical degree from the University of Loyola, Chicago, in 1918.

Dr. Flores spent six months in practice with Dr. C. T. Granger at Rochester and a year at Claremont, Minnesota, before establishing his practice at Dodge Center in 1921. In 1926 he became a naturalized citizen of the United States. From 1926 to 1933 he was Dodge County physician and from 1930 to 1932 was mayor of Dodge Center. He was also a member of the staff of the Owatonna Hospital, the Steele County Medical Society, the Minnesota State and American Medical Associations. He was a member of the Catholic Church and held membership in the Commercial Club of Dodge Center. His hobby consisted of wood working.

Dr. Flores married Minerva Benson, February 25, 1921, in Joliet, Illinois. He is survived by his widow and two daughters, Graciela M. and Virginia M. Flores, and a brother, Dr. M. A. Flores of Rosemount, Minnesota.

FRANCIS GUSTAVE LAGERSTROM

Dr. Francis Gustave Lagerstrom, Minneapolis, died March 13, 1943, at the age of sixty-seven.

Dr. Lagerstrom was born in Sweden in 1875, but came to this country fifty years ago. He received his medical education at the Kansas Medical College, Topeka, Kansas, completing the course in 1899.

After practicing at Lindstrom, Minnesota, for nine years, he moved to Minneapolis where he practiced until his retirement several years ago.

GUSTAV H. LUEDTKE

Dr. Gustav H. Luedtke of Fairmont died at his home March 18, 1943.

Dr. Luedtke was born November 18, 1870, in Blue Earth County, Minnesota. He received his early education at Mankato and his medical education at the University of Minnesota, graduating in 1899.

He served in the Medical Corps of the United States Army for twenty months during World War I and was a member of the Blue Earth Valley Medical Society and the Minnesota State and American Medical Associations.

CHARLES W. SIMISON

Dr. Charles W. Simison, a resident of Hawley, Minnesota, for the past thirty-five years, died March 6, 1943, in a Moorhead hospital following an illness of two years.

Dr. Simison was born in Mercer, Pennsylvania, April 3, 1878. After engaging in milling in Clinton, Missouri, for a number of years he attended the University of Missouri where he received his medical degree in 1907.

Dr. Simison practiced in Frazee, Minnesota, for a year before moving to Hawley in 1909. He served at one time on the Hawley Water and Light Commission and was a member of the sanitarium commission in Clay and Becker Counties. He was a member of the Clay-Becker County Medical Society and of the Minnesota State and American Medical Associations. He was also a member of the Methodist Church.

Surviving him are Mrs. Simison and three sons, Dr. Carl Simison of Barnesville, Dr. E. Victor Simison of Pocatello, Idaho, and Parker C. Simison, a pharmacist, of Warren, Michigan.

Reports and Announcements

WAR CONFERENCE

The medical, surgical and industrial hygiene experts who are so ably safeguarding the well-being of more than 20 million industrial workers have agreed to pool their knowledge and exchange their experiences regarding the many new and complex problems of today's wartime production. For this purpose their organizations—the American Association of Industrial Physicians and Surgeons, the American Industrial Hygiene Association, and the National Conference of Governmental Hygienists—are combining their annual meetings in a four-day "War Conference" at Rochester, New York, May 24-27, 1943. Among the problems to be discussed from a practical standpoint are:

The mass entry of women into industry;

Older-age employes, with their various associated problems; proper placement and employability considerations of the 4F rejectees;

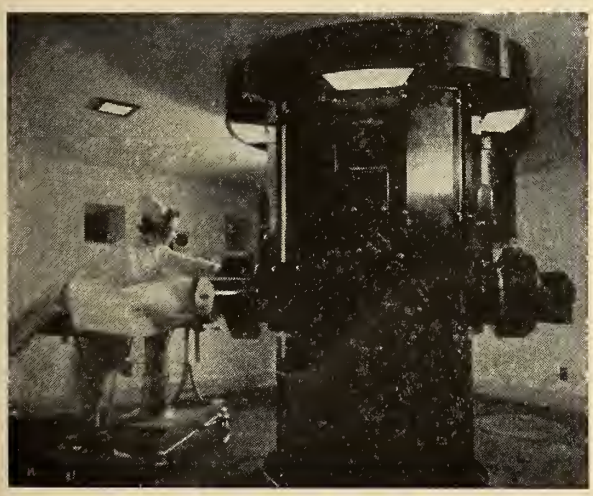
Rehabilitation and proper employment of those already discharged from the military services because of disabling conditions;

Toxic and other hazards from new substances, new processes, and the use of substitute materials;

Absenteeism; fatigue; nutrition;

Effects of long hours; double shifts; two-job workers; overtime; increased industrial accident rates;

Advances in the treatment of illnesses and injuries, and many others.



This joint meeting will be a report on the state of the nation, by the men who know, in matters of industrial health. Dr. William A. Sawyer, Medical Director of Eastman Kodak, is General Chairman; Dr. James H. Sterner and Lieut. Comm. J. J. Bloomfield are arranging the programs for the industrial hygienists.

Physicians and surgeons, hygienists, engineers, nurses, executives—all who are interested in the probems of industrial health and their solution—are invited to attend as many of the sessions as they can arrange for; no registration fee is required.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club, Saint Paul, Tuesday, March 9, 1943. The dinner meeting was addressed by Dr. Miland E. Knapp on the subject, "The Physiological and Pathological Basis of the Kenny Concept of Poliomyelitis." Dr. Alfred W. Adson is president of the Society and Dr. Royal C. Gray, secretary-treasurer.

WASHINGTON COUNTY SOCIETY

The regular meeting of the Washington County Medical Society was held on March 9 at Stillwater.

After the regular business had been transacted, and a report given of the County Officers' Meeting in Saint Paul, Dr. Edward Schons of Saint Paul gave a talk on "X-ray Treatments." He presented this highly scientific subject in a thorough and interesting manner.

MINNESOTA ACADEMY OF MEDICINE

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, January 13, 1943. Dinner was served at 7 p.m. and the meeting was called to order at 8:10 p.m. by the President, Dr. Harry Zimmerman.

Forty-eight members and two guests were present.

There was no new or old business to come before the Society, and the reading of the minutes of the December meeting was dispensed with.

Dr. Martin Nordland, Minneapolis, then gave his address as Retiring President, which consisted of a lantern slide talk on "Unusual Lesions of the Neck."

E. V. Kenefick, M.D., Secretary.

INVALID DIETS AND FOOD RATIONING

Of interest to all who are concerned with diets for invalids is Ration Order 13, issued by the Office of Price Administration under the date of February 9 1943. This order covers all canned, dried, and frozen fruits and vegetables.

Article II, Section 2.5 of the order reads as follows:

"Consumers who need more processed foods because of illness may apply for more points.

(a) Any consumer whose health requires that he have more processed foods than he can get with War Ration Book Two, may apply for additional points. The application must be made, on OPA Form R-315, by the consumer himself or by someone acting for him, and may be made in person or by mail. The application can be made only to the board for the place where the consumer lives. He must submit with his application a written statement of a licensed or registered physician or surgeon, showing why he must have more processed foods, the amounts and types he needs during the next two months, and why he cannot use unrationed foods instead.

(b) If the board finds that his health depends upon his getting more processed foods, and that he cannot use or cannot get unrationed foods, it shall issue to him one or more certificates for the number of points necessary to get the additional processed foods he needs during the next two months."

The application form referred to above, OPA Form R-315, is apt to be somewhat confusing to patients. It is titled "Sugar Special Purpose Application" and was developed primarily to meet the need for home canning. It is being used temporarily, until a more adequate form can be gotten out.

It is anticipated that the procedure indicated in Section 2.5 above may be changed somewhat in the future, in which case due notice will be provided.

WOMAN'S AUXILIARY

Mrs. Raymond J. Josewski, *President*
Stillwater, Minnesota
Mrs. W. H. Rucker, *Publicity Chairman*
Minneapolis, Minnesota

State Board

The Woman's Auxiliary of the Minnesota State Medical Association held its midwinter board meeting, February 26, in Saint Paul, at the Women's City Club.

The inspiring reports of the county presidents showed the various interests of the doctors' wives in these war days. Aside from surgical dressing groups, nutrition, home nursing and first aid classes, the county groups are sponsoring speakers' bureaus as part of their public relations plans.

Two new and very worthy projects this year are the collections for the medical and surgical Relief Society and the staffing of booths selling war stamps and bonds.

Mrs. E. C. Eshelby of Saint Paul was appointed to represent the State Medical Auxiliary on the Civilian Defense Board.

A nominating committee was elected with Mrs. H. Klein of Duluth, chairman.

St. Louis County

The regular monthly luncheon meeting of St. Louis County Medical Auxiliary was held March 9 at the home of Mrs. A. G. Spang of Duluth. The speaker was Dr. C. A. Shere, County Health Officer, who gave a survey of health conditions in St. Louis County. Mrs. Richard Bardon, one of the auxiliary members, then spoke on the American Red Cross.

Park Region

The Park Region Auxiliary voted to pay dues for the six members whose husbands are in the armed forces. Mrs. Lewis, president, attended the midwinter State Board Meeting in Saint Paul.

A large number of auxiliary members attended the lecture given by Dr. William A. O'Brien at a banquet meeting at the River Inn in Fergus Falls on March 1.

Hennepin County

The March meeting of the Hennepin County Auxiliary was devoted to discussion of gardens for victory led by Dr. Currence from the University Farm Campus.

Mrs. J. M. Hall, vice president of Hennepin County Auxiliary, is completing the year's work for Mrs. James A. Johnson who has been ill.

The membership is looking forward to entertaining the State Auxiliary in May in Minneapolis.

Upper Mississippi

Mrs. C. E. Carlson of Aitkin was elected president of the Upper Mississippi Women's Auxiliary at a meeting held in February. Mrs. J. J. Radcliff of Aitkin was chosen president-elect; Mrs. T. Eyres of Pequot Lakes, vice president; Mrs. Glen Leenhuis of Aitkin, secretary, and Mrs. W. E. Fitzsimons of Brainerd, reëlected treasurer.

Of General Interest

Lieutenant Wilford F. Widen of Minneapolis has been assigned to the U. S. Naval Hospital at San Diego, California.

* * *

Dr. and Mrs. Harry C. Jensen of Minneapolis are spending the midwinter months on vacation in Miami, Florida.

* * *

Dr. T. J. Bloedel closed his offices in Gaylord, March 1, to become associated in practice with Dr. A. Neumeier at Glencoe.

* * *

Dr. R. T. Edwards, who has practiced medicine at Elysian since 1914, left in March for Bigfork, Montana, where he will make his home with his sister.

* * *

Dr. T. G. Wellman of Lake City is now stationed with the Medical Corps of the Army Air Corps at Miami Beach, Florida. Dr. Wellman has the commission of First Lieutenant.

* * *

Dr. R. L. Schmidtke recently became associated in practice with Dr. F. E. Bureh of Saint Paul and is in charge of the ophthalmology clinic at the Wilder Dispensary, Saint Paul.

Dr. A. A. Giroux, formerly of Moose Lake, ha moved to Grove City, where he will continue the prac tice of medicine.

* * *

Dr. Carl W. Waldron of Minneapolis has been ap pointed editor of *The Journal of Oral Surgery*, a new publication sponsored by the American Dental Associa tion.

* * *

Dr. Laurence H. Cady has been elected chief of staf of St. Andrew's Hospital, Minneapolis. Dr. Ragnar T Soderlind was elected vice president and Dr. Ferdinand A. Zinter, secretary-treasurer.

* * *

Dr. F. C. Gibbons of Comfrey is building a hospita with a capacity of twelve rooms, increasing his office space and allowing six rooms for the accommodation of patients. Construction of the building was begun in March.

* * *

Dr. H. A. Burns, formerly director of the State Sanatorium at Ah-Gwah-Ching, has been placed in charge of tuberculosis problems in all State Institutions. He

is succeeded at Ah-Gwah-Ching by Dr. F. F. Callahan, formerly head of the Pokegama Sanatorium, Pokegama.

* * *

Dr. Gordon R. Kamman of Saint Paul read a paper before the American Orthopsychiatric Association in New York City, February 22, 1943. The title of his paper was "The Rohrschach Method as a Therapeutic Agent."

* * *

Dr. D. L. Jacobs of Willmar has been commissioned a Lieutenant (sg) in the United States Navy Reserve and reported for duty at San Diego, California, April 5. Dr. Jacobs has been associated in practice with his father, Dr. J. C. Jacobs, at Willmar since 1935.

* * *

Lieutenant Lynn M. Hammerstad, flight surgeon attached to the naval aviation cadet selection board, has been ordered to duty in the western Pacific war theater. Lieutenant Hammerstad was on the staff of the Minneapolis General and Swedish Hospitals, Minneapolis, before entering the Navy in 1939.

* * *

Lt. Col. Richard B. Hullsiek, Saint Paul, who has been medical officer for Selective Service for Minnesota, left March 4 for duty in the Seventh Service Command, Omaha. Colonel Hullsiek has been with the National Guard since 1927. He is succeeded in Minnesota by Major Robert Radl.

* * *

Dr. Wm. C. Heiam, the first physician to locate in Cook, Minnesota, recently completed his fifteenth year of practice in this northern Minnesota town. He started his practice in a one-room office, to which more rooms were added later, now forming the present hospital building in Cook.

* * *

With the winning of his "wings" by Major Edwin G. Benjamin, the Hennepin County Medical Society now numbers five flying members, namely—Major Benjamin, Lieutenant Colonel Lawrence Larson, Lieutenant Frederic Wipperman, Lieutenant Commander Edward Colp and Major Reuben Berman.

* * *

Dr. Herman O. McPheeters is the new president of the Minneapolis Surgical Society, succeeding Dr. Richard R. Cranmer. Other officers elected are: Dr. Daniel A. MacDonald, vice president; Dr. Robert F. McGandy, treasurer; Dr. John M. Feeney, secretary, and Dr. Fred A. Olson, recorder.

* * *

The following subjects were presented at the Interdepartmental Seminar of the Medical School held in the Eustis Amphitheatre, University of Minnesota, Wednesday evening, March 24:

"Unusual Association of Familial Hemolytic Jaundice and Subacute Combined Degeneration in Elderly Man"—C. J. Watson, M.D., Department of Medicine.

"Calcium and Phosphorus Balance Studies in a Case of Idiopathic Hypoparathyroidism"—R. G. Sprague, M.D., and M. H. Power, Ph.D., Mayo Foundation.

"Experimental Mammary Cancer in Mice"—John Bittner, Ph.D., Division of Cancer Biology, Medical School.

Trueta, M.D. Formerly Director of Surgery, General Hospital of Catalonia, University of Barcelona; Assistant Surgeon (E.M.S.), Wingfield-Morris Orthopædic Hospital, Oxford; Acting Surgeon-in-Charge, Accident Service, Radcliffe Infirmary, Oxford. With introduction by Owen Wangensteen, M.D., Minneapolis, Minnesota. 441 pages. Illus. Price, cloth, $6.50. St. Louis: C. V. Mosby Co., 1943.

FUNDAMENTALS OF PSYCHIATRY. Edward A. Strecker, M.D., Sc.D., F.A.C.P. 201 pages. Illus. Price, $3.00. Philadelphia; J. B. Lippincott Co., 1942.

Dr. Strecker has written a concise presentation of the modern concept of psychiatry and its relationship to all fields of medicine. It will be of great practical value to the medical student as well as to all doctors who lack psychiatric training. It is particularly appealing because of its lack of abstract terms and psychiatric patter in general. It is these faults which usually cause the average person to abhor psychiatry, and Dr. Strecker has done a good job in minimizing them.

OVARIAN TUMORS. Samuel H. Geist, M.D. New York: Paul B. Hoeber, Inc., 1942. 527 pages. Illus. Price $10.50.

This is a very important subject presented by a national authority in a 500-page volume of very interesting reading.

In the opening chapter the author presents the embryology, the anatomy and the physiology of the ovary. Then he presents all the well-known as well as the rarer forms of ovarian tumors according to the embryological histologic structure from which they arise; a classification presented by Schroeder. Each tumor is discussed as to its frequency, gross and microscopical pathology, its clinical aspects and therapy.

He has a chapter on ovarian tumors in children, one on ovarian tumors in pregnancy; a chapter on diagnosis and one on treatment.

His chapter on general considerations is very good and complete.

A very lengthy bibliography follows each chapter.

SYNOPSIS OF PATHOLOGY. By W. A. D. Anderson. 661 pages, 294 test illustrations and 17 color plates. Price, $6.00. St. Louis: C. V. Mosby Company, 1942.

This volume is an excellent condensation of the whole field of pathology. It is surprising that the author could cover so much ground in such a compact volume. The linkage of pathology with clinical medicine is stressed throughout the book. The illustrations are excellent. In fact, it is rare to see a photographer with such an esthetic sense in the arrangement of gallstones as in the photograph on page 348.

It seems to this reviewer that the whole subject of pathology could be simplified by classifying the diseases of organs under five headings: first, acute inflammation; second, chronic inflammation; third, benign tumors; fourth, malignant tumors; and fifth, anomalies, mechanical defects, etc. If the various organs were reviewed in this manner, there would be much less repetition and students would have much better concept of the diseases of the various organs. It certainly helps the student to get a better grasp of the differential diagnosis of diseases. The above paragraph is not meant as a criticism of the volume, as the development of the subject is one of individual preference.

This volume is highly recommended for an up-to-date review of pathology.

CHARLES E. REA, M.D.

Uncorrected *visual defects*, that would cause productive deficiency, have been found in one person out of every four applying for work in certain factories.

Castor-bean growing will be greatly increased in 1944, with some 3,000,000 pounds of seed expected to be produced this season from 10,000 acres in eight Midwestern states under a federal government plan.

An old disease takes on new entity:

The Kenny Concept of

INFANTILE PARALYSIS

and its Treatment

By JOHN F. POHL, M.D.
In Collaboration With
SISTER ELIZABETH KENNY
Foreword by
FRANK R. OBER, M.D.

THE CONCEPT: A completely new theory of the symptomatology and effects of INFANTILE PARALYSIS. It is the result of thirty years of keen observation, meticulous study and diligent labor by Sister Kenny. Without doubt it is the most important contribution ever made toward the control of this dread disease.

BASIS OF PROOF: Clinical results over a period of several years, both here and abroad, are direct evidence of the success of Sister Kenny's treatment. Her work has been approved by practically the entire medical profession. The National Foundation for Infantile Paralysis endorses it. Eminent orthopedic surgeons accept and praise it.

THE TREATMENT: Step by step, this new book on INFANTILE PARALYSIS takes the reader through nearly four hundred pages of detailed instructions in Sister Kenny's treatment, with more than one hundred explanatory photographs. While the book is designed for easy reading, it is distinctly a textbook for the medical profession. Every physician should own a copy. In his hands it becomes a weapon of defense on the Home Front.

Size 6 x 9 inches. Cloth Bound.
368 pages. 114 Explanatory Photographs.
PRICE, $5.00 postpaid

OPTIMUM NUTRITION FOR BABY...

MINIMUM TIME FOR DOCTOR...

with this complete liquid infant formula!

BIOLAC SUPPLIES milk proteins, milk minerals, iron, and vitamins A, B_1, B_2 and D in amounts which equal or exceed recognized requirements for infants. Thus with the sole exception of vitamin C, Biolac provides *complete* nutrition for the bottle-fed baby.

Biolac is a real timesaver for overworked doctors, too! *No carbohydrate or other extra formula ingredients to calculate!*

Also, with Biolac there is less chance of upsets due to errors in preparing formulas. Less chance of formula contamination, too, because Biolac requires only simple dilution with boiled water, as you prescribe.

NO LACK IN BIOLAC

Borden's complete infant formula

● *Biolac is prepared from whole milk, skim milk, carbohydrates—Vitamin B_1, concentrate of Vitamins A and D from cod liver oil, and ferric citrate. It is evaporated, homogenized, and sterilized. For professional information, write Borden's Prescription Products Division, 350 Madison Avenue, New York, New York.*

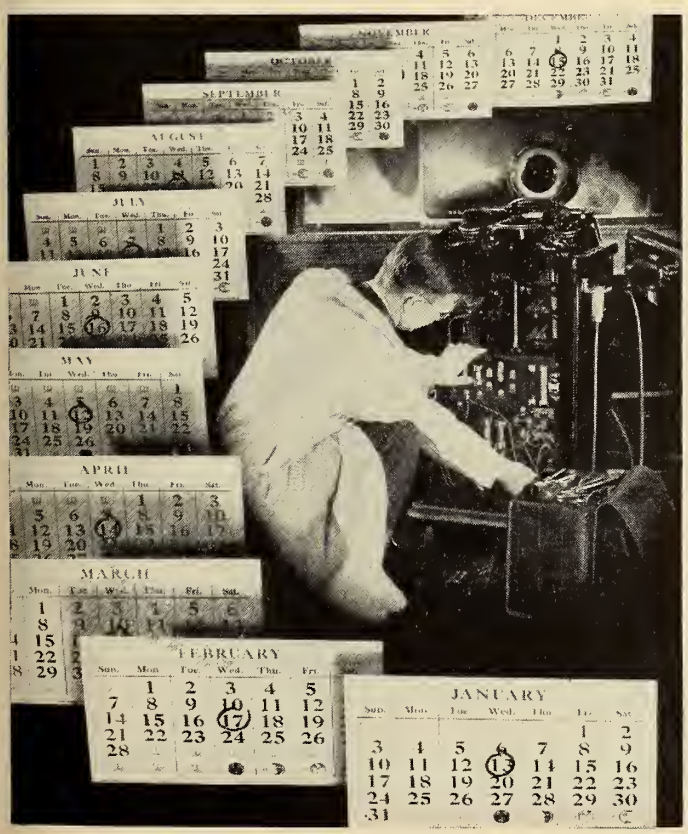
NOT A WAR-BORN IDEA

Personalized Field Service on G-E Equipment Has Prevailed for Many Years

It is important that x-ray and other electromedical equipment be kept in tip-top operating condition during these busy days in hospitals, clinics, and physicians' offices. And to users of G-E equipment the need for expert technical and maintenance service in this wartime period has presented no problem. They continue to get it from the same G-E branch offices and regional service depots that have taken care of them for many years past.



In other words, this idea of G-E field service is not something set up *just for the duration.* It is considered quite as important to G-E customers in peacetime as well.

G-E Periodical Inspection and Adjustment Service, for example, is a low-cost, year-round service that keeps thousands of G-E x-ray and electromedical units at highest operating efficiency at all times. Thus investments in fine equipment are protected, to preclude costly and annoying breakdowns.

Therefore, to present and future users of G-E equipment, this competent field service will always be available—in wartime and peacetime, both.

Good News!

★ DEXTRI-MALTOSE

WITH YEAST EXTRACT AND IRON now measures 4 (instead of 6) level tablespoonfuls to the ounce

and

★ is packed 16 oz. (instead of 12) per tin

and

★ each ounce supplies 2.8 mg. iron

and

★ each ounce supplies .3 mg. thiamine

and

★ each ounce supplies .1 mg. riboflavin

During the baby's first six months, this product alone supplies to the milk formula more iron than the infant requires

and

more thiamine than the average infant requires.

Dextri-Maltose With Yeast Extract and Iron is supplied now in 1-lb. and 5-lb. cans

ALL AT NO INCREASED COST TO THE PATIENT

MEAD JOHNSON & CO.
EVANSVILLE, IND., U.S.A.

The art of anatomic illustration entered a new epoch upon the publication of the Tabulae Anatomicae of Giulio Casserio (Venice, 1627). This female figure is one of Casserio's most beautiful copperplates.

THEELIN AQUEOUS SUSPENSION

For patients requiring high potencies, and for those who do not tolerate oil injections.

THEELIN AQUEOUS SUSPENSION provides the same pure, natural crystalline estrogen as Theelin in Oil, and the same effective clinical results may be expected in the treatment of menopausal syndrome and other conditions due to diminishing estrogenic secretion. Theelin Aqueous Suspension is administered intramuscularly. Normal saline solution—no suspending agent—is used in preparing this product and the ampoule need only be shaken gently before the preparation is drawn into the syringe.

The uniform potency of Theelin is certified by the Laboratories of both Parke, Davis & Company and St. Louis University. Kapseals Theelol (Oral) and Theelin Suppositories (Vaginal) are available for maintenance therapy and for use in milder hypogonadal conditions.

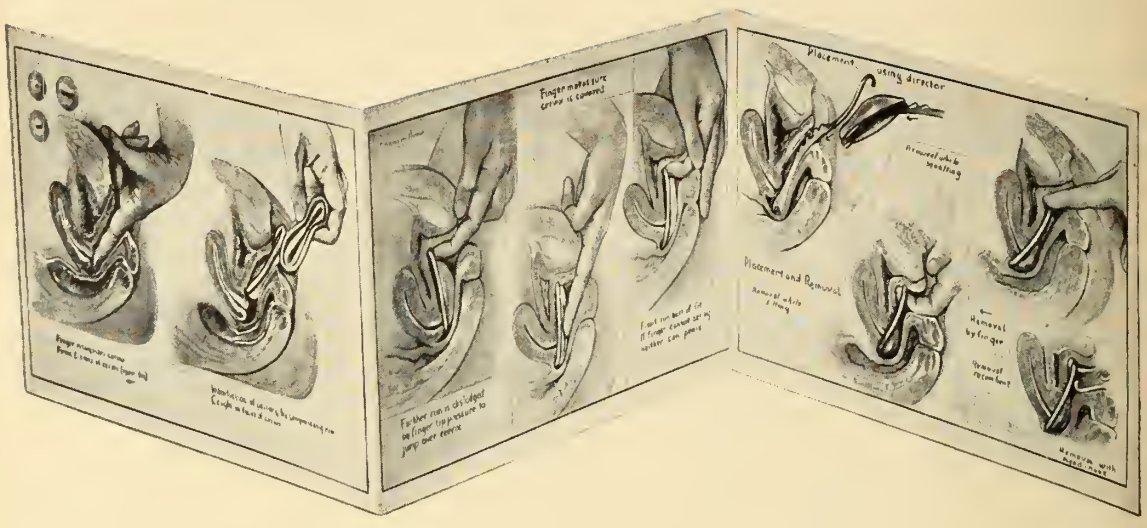
•

THEELIN AQUEOUS SUSPENSION

1-cc. ampoules, each cc. containing 2 mg. (20,000 I.U.) of Theelin suspended in normal saline solution.

•

THEELIN IN OIL



1-cc. ampoules in strengths up to 1 mg. (10,000 I.U.) of Theelin per cc.

THE RISING CURVE OF PEPTIC ULCER IN WAR

"Peptic Ulcer ranks high as a cause of disability for military service. It . . . leads all other digestive diseases as a cause for discharge from the Regular Army."

Kantor, J. L.: Digestive Disease and Military Service, Jnl. A. M. A., Sept. 26, 1942.

THE increased incidence of peptic ulcer among the armed forces, defense workers and civilians today confronts medicine as a major problem.

Of the various types of therapy used to control this problem none has proved itself more valuable than CREAMALIN, brand of aluminum hydroxide gel.

CREAMALIN, the first aluminum hydroxide gel to be made available to physicians, was also the first to be Council-accepted. CREAMALIN contains approximately 5.5% aluminum hydroxide.

ACCEPTED
AMERICAN MEDICAL ASSN.
Council on Pharmacy and Chemistry

CREAMALIN
REG. U. S. PAT. OFF.
Brand of Aluminum Hydroxide Gel

Therapeutic Effects of CREAMALIN

- **Pronounced antacid action of 12 times its volume of N/10 HCl in less than 30 minutes (Toepfer's reagent)**
- **Prolonged action in contrast to fleeting effect of alkalies**
- **Non-alkaline; non-absorbable; non-toxic**
- **No acid rebound; no danger of alkalosis**
- **Prompt and continuous pain relief in uncomplicated cases**
- **Rapid healing when used with regular ulcer regimen**
- **Mildly astringent; may reduce digestive action, thus favor clot formation**
- **Demulcent; gelatinous consistency affords protective coating to ulcer**

Modern non-alkaline therapy for peptic ulcer and gastric hyperacidity

What is Luzier's Service?

In effect, it is a means by which thousands of women improve their appearance and maintain its loveliness. Specifically, it is a system of selecting cosmetics to suit individual requirements and preferences. It is based on a Selection Questionnaire whose answers serve as a guide to our Selection Department. It is made available by Cosmetic Consultants who are trained to assist you with the selection of suitable types of Luzier products and to show you how to apply them to achieve the best results, the loveliest appearance. A card addressed to Luzier's, Inc., Kansas City, Missouri, will be forwarded to the Distributor of our products in your vicinity. It will be her pleasure to call on you at your convenience and without obligation on your part to acquaint you with the many delightful features of Luzier's Service.

THE PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

Responsibilities, Accomplishments and Future Problems

HAROLD S. DIEHL, M.D.
Member, Directing Board, Procurement and Assignment Service
Dean of the Medical Sciences, University of Minnesota
Minneapolis, Minnesota

A LITTLE more than a year has passed since October 30, 1941, when the President of the United States, by executive order, created the Procurement and Assignment Service for Physicians, Dentists and Veterinarians. The reason for this order was the realization that adequate medical and health services for both military and civilian populations are essential for the effective prosecution of the war. The action was taken upon the recommendations of the American Medical Association, the American Dental Association, the Surgeon Generals of the Army, the Navy, and the United States Public Health Service, and Mr. Paul V. McNutt, as Chief of the Office of Defense, Health and Welfare Services. This makes the Procurement and Assignment Service, morally at least, responsible both to the government of the United States and the medical, dental, and veterinary medical professions of this country. In view of this it is appropriate that a brief report should be made at this time of the accomplishments of this service to date and the problems and responsibilities remaining for 1943.

In general terms, the responsibility of this Service is to plan for the distribution of the services of the physicians, dentists and veterinarians of this country so as to meet as effectively as possible the needs of both the armed forces and the civilian population during the war.

The plan of procedure contemplated by the Directing Board at its early meetings was to proceed in an orderly manner to appraise the medical personnel of this country, their qualifications, and their availability for military or civilian services in case of war. Unfortunately, the ink was hardly dry on the President's executive order before we were plunged into the midst of war. This made it necessary for the Procurement and Assignment Service to formulate policies, develop its organization, and begin to function all at the same time. There was no blueprint to follow, no past experience upon which to draw.

Organization and Administrative Relationships

Although its establishment antedated that of the War Manpower Commission, the Procurement and Assignment Service was made administratively responsible to that organization immediately upon its creation. This made the Procurement and Assignment Service what might be called the Medical division of the War Manpower Commission. Although official channels between the Procurement and Assignment Service and the War and Navy Departments are through the Director of the War Manpower Commission, the great majority of the contacts with the Army and the Navy are made directly

Read at the War Session of the American College of Surgeons, St. Paul, Minnesota, March 1, 1943.

and informally with the Offices of the Surgeon Generals of these services. In fact, the Directing Board of the Procurement and Assignment Service holds monthly meetings with the Surgeon General of the Army, the Surgeon General of the Navy, the Surgeon General of the United States Public Health Service, the Director of Selective Service and such members of their staffs as they elect to accompany them. The results of these conferences and informal relationships have been so satisfactory that very few communications through official channels have been necessary. Without this splendid understanding and effective coöperation on the part of these services, the task of the Procurement and Assignment Service would have been an impossible one.

The organization of the Procurement and Assignment Service consists of a Directing Board, a Central Office in Washington, a Consultant's office in the headquarters of the American Medical Association in Chicago, and Corps Area and State Committees, with local, county, or district committees serving in an advisory capacity. The physicians on these various boards and committees have given unselfishly and unstintingly of their time and services. Without compensation, at great personal sacrifice, and at times in spite of uninformed or malicious criticism, these men have rendered and are continuing to render an invaluable and patriotic service to our country in its war effort. It is primarily to the chairmen and the members of the State and local Procurement and Assignment Service committees that the real credit for the accomplishments of this service belongs.

With the American Medical Association and the various state medical societies, the Procurement and Assignment Service has a most intimate, though unofficial, relationship. In 1940 the American Medical Association at great expense and effort prepared a roster of all the physicians in the United States with detailed information in regard to their training, experience and qualifications. This invaluable roster was made available to the Procurement and Assignment Service immediately after its organization. In addition, the American Medical Association has made its staff and facilities available at all times to aid in the work of the Procurement and Assignment Service. In like manner, state medical societies not only have coöperated wholeheartedly, but in many instances have provided a large portion of the expenses and carried much of the work and the State and local Procurement and Assignment committees. Without this assistance and support, the work of the Procurement and Assignment Service could not possibly have been carried out. To these various medical associations we acknowledge our deep indebtedness.

Accomplishments of 1942

With the rapid expansion of our armed forces last year, the first responsibility of the Procurement and Assignment Service was clearly to cooperate with the Army and Navy in the recruitment of the medical officers which they needed. Our boys, and now our girls, whether they be in Africa, India, Guadalcanal, Australia, Alaska, or the continental United States, must be provided with the best of medical care. I am sure that everyone would agree that the provision of medical services to those who are risking and in many cases sacrificing their lives in defense of our country deserves first priority in the allocation of physicians.

Second, probably, comes the need of the medical schools for teachers to train more physicians under the accelerated program of medical education. These institutions, which have been mobilized 100 per cent for the war effort, serve as the only source of supply for additions to or replacements of physicians for both the armed forces and the civilian population.

Next, in order of priority, comes the provision of medical care for workers in the war industries. These workers must be kept on the job, producing the materials of war without which armies and navies are helpless in modern warfare.

This leaves as last on our priority list the needs of the general population for medical services. This does not mean that the civilian population will have to get along with what is left after the armed forces, the medical schools and the war industries have taken all the physicians that they want. The effective prosecution of a modern war requires the mobilization of the entire resources of the nation in support of the war effort. Under such circumstances, it is clearly necessary that a sufficient number of physicians be retained to provide essential medical services for the civilian population. Recognizing

this, the Army and the Navy have agreed not to grant commissions to physicians declared essential by the Procurement and Assignment Service for civilian medical care. Likewise, local Selective Service boards have been directed by National Headquarters to secure the recommendation of the Procurement and Assignment Service whenever they are considering the classification of a physician, dentist or veterinarian.

Recruitment of Physicians in 1942

At the outbreak of war there were approximately 13,000 medical officers on duty in the Army and the Navy. At the end of 1942, approximately one year later, this number had increased to over 42,000. The recruitment of such a large number of physicians in a short period of time was a colossal undertaking. Except for a few single men who came under the jurisdiction of Selective Service, there was no authority to compel physicians to go into the Service. What has been accomplished has been entirely on a voluntary basis. The Procurement and Assignment Service possesses no authority to say to a physician that he must go into the service or that he must stay at home. Some of the Army recruiting boards in their zealous efforts to recruit physicians presumed and even threatened to use authority which they did not possess. Actually neither these boards nor the Procurement and Assignment Service has authority to exercise compulsion upon anyone.

Early in last year it seemed for a time that physicians were slow in responding to the call for their services. But by the end of the year, over 50 per cent of the practicing physicians under 45 years of age had entered the armed services. No other professional group in this country has ever been called upon for such public service or responded to a call so magnificently.

During the first world war, the recruitment of physicians for the Army and Navy was carried on with little or no consideration for the needs of the civilian population. Many areas and communities were left without medical service, while in other areas excessive numbers of physicians remained in civilian life. To help prevent a similar situation this time, the Procurement and Assignment Service established quotas as to the number of physicians which each state was expected to supply in 1942. These quotas represented the proportionate share of the 42,000 medical officers requested by the armed forces, which it seemed equitable for each state to provide, taking into consideration the population of the state, the number of physicians in civilian practice, their ages, distribution, etc. These quotas for states with relatively few physicians in relation to population required only 10 to 15 per cent of the practicing physicians; while at the other end of the scale, the quotas of states such as New York and Illinois represented up to 30 per cent of the physicians actively engaged in civilian practice.

The country as a whole and all but five individual states met or exceeded the quotas assigned to them for 1942. From a few areas, particularly in the South, too many physicians have gone into service, leaving the civilian population without adequate medical care. Some of these physicians held commissions in the Reserve Corps of the Army or Navy and were called to active duty; others volunteered early before the Procurement and Assignment Service program became operative; others were released by the State Procurement and Assignment Committees because it seemed that there were sufficient numbers of doctors remaining to care for the civilian population. In some instances, these calculations were upset by illness or death among the remaining physicians or by the unanticipated influx of large populations in connection with war industries or war activities. I know of one county in which there were three physicians. The youngest of these was declared "available" for military service. Subsequently one of the two remaining physicians has died, and the other has had a "coronary attack," which seriously limits his availability for practice. The result is that this county is now critically short of medical service.

The Maintenance of Civilian Medical Services

In order to safeguard civilian medical services, the chairmen of the State Procurement and Assignment Committees have been directed to designate as "essential" those physicians considered necessary for the provision of essential civilian medical services.

To aid in this, *medical schools* have been authorized to submit lists of their faculty members, marking as "available" those whom they could release for service with the armed forces but listing as "essential" those who constitute the minimum staff necessary to conduct a sound

teaching program. These reports specify the subjects that each individual is teaching and the amount of time he was devoting to such teaching. All lists of "essential teachers" as submitted by the medical schools are reviewed by the Medical Education Committee and the Allocation Committee of the Procurement and Assignment Service. The opinion of these committees in regard to the lists is then sent to the chairmen of the respective State Committees who are responsible for decisions as to who is "available" and who "essential." The objective is to retain adequate teaching staffs for the medical schools, but to do so without withholding from military service more than the minimum number of men who are physically qualified for military service.

Analysis of the medical school lists which were submitted last summer for the current academic year showed that up to that time 21 per cent of the physicians on medical school faculties were in Army or Navy service as compared to 12 per cent of all the physicians in the United States. In addition, the medical schools listed as "available" 25 per cent of the physicians of military age remaining on their staffs.

Industrial medical service assumes increasing importance in connection with the war. The criteria as to the conditions under which physicians in industry should be considered "essential" were prepared by the Committee on Industrial Health of the Procurement and Assignment Service. This Committee recommended that essential industrial medical services be continued but that physically fit young physicians of military age serving in industry should be replaced as rapidly as possible by those who are not physically fit or otherwise ineligible for military service.

Public health services must be maintained for the protection of the health of the armed forces as well as of the civilian population; yet the staffs of these services contained many physicians with training and experience urgently needed by both the Army and the Navy. Epidemiologists, parasitologists, bacteriologists, statisticians, and public health administrators are urgently needed for the prevention and control of diseases among our soldiers who are serving in all parts of the world. In order that public health services might be maintained and yet as many as possible of these specialists relieved, all state, city and county health departments were requested to prepare lists of personnel, indicating which ones of military age could be released for military service and which ones are considered as essential for the effective functioning of the health department. These lists are reviewed by the Public Health Committee of the Procurement and Assignment Service.

Hospitals.—Most of the members of the clinical staffs of hospitals are physicians practicing in the community and are designated as "available" or "essential" on the basis of the importance of their services to the community as a whole rather than to any individual hospital. On the other hand, in many of the large charity and teaching hospitals, certain residents and physicians in charge of special services, such as the x-ray and laboratory departments, are essential both for the clinical instruction of medical students and for the adequate care of the hospital patients. With this group the problem again is to release as many as possible for service with the armed forces and still retain the minimum number essential for the proper functioning of the institution. To accomplish this, hospitals approved for residencies have been requested to prepare lists of residents and other physicians who were on full-time status or chiefs of large charity services, indicating those whom they consider to be the minimum essential staff of the hospital. These lists have been reviewed both by the Hospital Committee and the respective State Committees of the Procurement and Assignment Service.

"Boom Towns."—During the past year many towns have experienced a mushroom growth as a result of war industries or military or naval installations. Some of these have given rise to critical shortages of medical services. Numerous articles have been written about these areas, frequently with gross exaggerations as to their number and seriousness. In many instances the workers in these war industries are recruited from persons already residing in the area. In others, if the influx of population is not excessive, the physicians in the community are able to provide the necessary medical care. On the other hand, there are a number of areas in which the shortage of medical services is truly critical. I have visited one community which in a little more than a year has grown from 15,000 to 65,000 population and it is expected that by

July, 1943, the increase will reach 110,000. Another area which had approximately 40,000 population before the war now has 110,000 and is expected to have 145,000 by midsummer. In the country as a whole, there are a number of such areas.

Last summer and fall a number of agencies in Washington became concerned about the shortage of medical services in these areas, and numerous conferences were held to define lines of responsibility and to outline procedures to deal with the situation. On the basis of these conferences, the Directing Board of the Procurement and Assignment Service formulated certain policies in regard to the investigation of the need and the provision of medical care in critical shortage areas. These policies, which were approved by the United States Public Health Service, by the Trustees and the War Participation Committee of the American Medical Association and by the War Manpower Commission, placed the primary responsibility for the investigation of these areas and for the formulation of plans to meet these needs upon the Procurement and Assignment Service and the local medical profession, with the coöperation and assistance of the United States Public Health Service. In approving these principles, the War Manpower Commission said, "This approval is given with the understanding that the plan places a grave responsibility on the organized medical profession, and that the Procurement and Assignment Service has the obligation of assuring that this responsibility is effectively discharged."

To meet these responsibilities, the Directing Board requested detailed reports from the State Chairmen concerning changes in population, the medical personnel, and the medical and health facilities available and needed in communities or areas in which there are war industries or war activities or in which there is a known or expected shortage of medical services. In investigating the needs of these areas, the State Procurement and Assignment Committees are advised to seek the "coöperation of the state medical societies, the state dental societies, the state health officers, of industry, of organized labor, and of other agencies, such as the State Defense Council, which should be able to make significant contributions to the solution of this problem." In addition, the Surgeon General of the United States Public Health Service has directed the regional representatives of this Service to cooperate in the conduct of these investigations.

When these investigations reveal a need for additional physicians or other medical or health facilities or personnel, the principles provide that: "Whenever possible civilian needs as determined by these committees should be met through local arrangements, resources, and agencies. In case assistance is needed for the organization, administration, or financing, of necessary medical services in these areas, the responsibility for formulating the plan best suited to each particular situation should devolve upon an agency which should include representatives of the state health department, the state medical society and the state dental society with the coöperation and support—financial and technical—of the appropriate federal agencies; the administration of such plans to be delegated to the appropriate official state agency." It is recognized that the United State Public Health Service is the federal agency which will be responsible for the provision of funds or personnel which may be required to provide the necessary health services in these areas.

In the formulation and execution of this program, there has been complete harmony and cooperation between the Directing Board of the Procurement and Assignment Service and the United States Public Health Service as represented by Surgeon General Thomas Parran and Assistant Surgeon General Warren Draper. Before the close of 1942, this program was inaugurated as a coöperative enterprise between the medical profession, the Procurement and Assignment Service, and the United States Public Health Service.

Problems of the Procurement and Assignment Service for 1943

The end of the year means little in war except to provide a convenient point at which to end and begin reports. Similarly, the responsibilities and the problems which faced the Procurement and Assignment Service in 1942 carry over into 1943. Changes in emphasis occur, but these are gradual and related to the over-all situation. The recruitment of additional physicians to serve with the armed forces and the maintenance of essential civilian medical services are still our major responsibilities. During the past year, however, there have been important

changes in the situation confronting us. A year ago we had what seemed to be an almost unlimited supply of physicians; the needs of the armed forces for medical officers appeared easy to fill; war industries were just beginning to draw workers and their families from far and wide; and there seemed no problem of providing medical care for the civilian population.

With the advent of 1943, an analysis of the physicians of the country revealed that the statement about our having 180,000 physicians was misleading; and that withdrawals from this group were already approaching the limit of the available supply. The figures show that we do have a total of approximately 180,000 physicians registered in the United States. Of these, however, approximately 15,000 occupy full-time positions in public health departments, medical schools, insurance companies, or other governmental or private agencies not engaged in the practice of medicine; 28,000 are over sixty-five years of age, and for planning purposes are counted as only one-third effective by the Procurement and Assignment Service; it is estimated also that approximately 5 per cent, or a total of 7,000 of the physicians under sixty-five are completely or partially ineffective; 3,000 are resident physicians in hospitals; and approximately 42,000 were in the armed forces on the first of January. This leaves only about 94,500 effective physicians remaining in civilian practice. There are areas in most states which have never had more than one doctor for two, three, or even more thousands of people. We cannot hope to bring about the millenium in these areas during the war when there is an over-all shortage of physicians. On the other hand, in areas in which a shortage of physicians has been created by the war a ratio of 3,000 or more people per physician is considered by the Directing Board as probably constituting a critical situation. On a basis of this over-all ratio of one physician for 1500 population, approximately 83,000 physicians are needed to provide essential medical services for the civilian population. This leaves only 11,500 physicians who can be considered as "available" from civilian practice in 1943 to enter the military services. In addition, between 4,000 and 5,000 hospital interns and residents will become available for military service during 1943.

Recruitment for the Armed Forces

On the basis of their established tables of organization, the authorized expansion of the Army and Navy in 1943 would require between 40,000 and 45,000 additional medical officers. In spite of this, both the Surgeon General of the Army and the Surgeon General of the Navy have accepted the above computations as to the number of physicians who can be safely withdrawn from civilian practice. This means that they will have to adjust their plans of organization and operation so as to get along with less medical officers than they consider ideal. Both the Army and the Navy, however, are willing to make these adjustments.

In accepting the recommendations of the Procurement and Assignment Service as to the number of physicians to be recruited from the civilian population in 1943, the Army and Navy have placed upon this Service, and through it upon the medical profession, the responsibility of recruiting available physicians up to this number.

As a guide in this recruitment, tentative state quotas for 1943 have been set up. These quotas are based upon the physician-population ratio in the state after the 1942 quota was met. Credit was given for physicians recruited in excess of the 1942 quota, while deficits on the 1942 quota were added to the new quotas. According to these computations, fourteen states have no quotas and only fifteen states have quotas of more than a hundred physicians for 1943.

The fact that some of these states have had no second quotas does not necessarily mean that no more physicians from these states should enter military service. Even in those states in which there is an over-all shortage of physicians, there probably are metropolitan areas from which some physicians can and should be released. If other areas within these states are critically short of physicians, efforts should be made to induce some of the available physicians from the metropolitan areas to move into these shortage areas. If they are unwilling to do so, they should be declared available for military service and persuaded to apply for commissions.

As a basis for future planning, State Procurement and Assignment Committees have been asked to re-appraise the physicians remaining in their states as to their availability or essentiality,

their age, professional qualifications, physical capacity, and family responsibilities. As soon as these surveys have been completed, summary reports will be sent to the Central Office of the Procurement and Assignment Service, and revision of certain state quotas may be made.

Recruitment Procedure

The Procurement and Assignment Service proposed and the Army agreed that recruitment in 1943 should be done by the Procurement and Assignment Service instead of by Army recruiting teams. Briefly summarized, the procedure agreed upon is as follows: The State Chairmen submit monthly lists of available physicians to the Central Office. From this office letters are sent to these physicians, requesting them to apply for commissions and enclosing cards addressed to the State Chairmen, indicating their preference for Army, Navy, or Air Corps service. The names of those choosing Army service are sent to the nearest Army Officer Procurement Board, which supplies the necessary application forms and authorizes physical examinations. A similar procedure is followed for those who prefer to serve in the Navy. In case a physician does not apply for a commission when requested to do so, it is the responsibility of the Procurement and Assignment Service, in coöperation with the local medical society, to induce him to accept the assignment which he has been given.

Some predict that it will be difficult to secure the number of physicians agreed upon for the armed forces in 1943. They point out that most of those who really want to serve are already in service. This is doubtlessly correct, but we feel certain that many more physicians will be willing to go when they are told specifically and individualy that their services are needed. For others some persuasion may be necessary. As a whole, the medical profession has responded magnificently to our country's call. It is but a very small minority who would place selfish interests above professional and patriotic responsibilities.

A few days ago, however, I heard of a young physically fit physician who left a hospital residency to go into private practice. To one who asked him about army service, he replied that his draft board would defer him. Upon such individuals it would be possible for the Army, Navy, and Selective Service to exert pressure. To do so, however, would require the issuance of general directives that would reflect unfavorably upon the medical profession as a whole. It is our hope that medical societies will set up local committees to coöperate with the Procurement and Assignment Service in the recruitment of those physicians of military age who are considered available for service with the armed forces. As a specific plan of procedure it is recommended that the officers of county medical societies act as committees to make personal contact with these physicians who are requested by the Procurement and Assignment Service to apply for commissions.

The time has come when every physically fit, available physician under forty-five years of age is needed to care for the boys who are risking their lives in the service of our country. Quoting a statement which Dean Thorald Sollmann of Western Reserve University made to a recent graduating class in his medical school: The time has come when "it doesn't matter much that someone else evades his obligation. Each must live with his own conscience; and he who has none is missing something. Patriotism is what you give, not what you get; and what *you* give, not what the other fellow gives or withholds. And if it should turn out, as it may in a topsy turvy world, that he gets the plums and you get the husks, well—, a good doctor can lead a useful and satisfying life anywhere and anytime without plums."

Meeting Civilian Medical Needs

The problems of civilian medical care are becoming increasingly acute as more and more physicians are taken into the armed forces. This country has more physicians in relation to population than any other country in the world, and there will be plenty available to provide essential, though not luxury, medical services for both the armed forces and for the civilian population if their services are properly distributed and utilized economically and efficiently. At the beginning of the war, there was approximately one effective private practitioner of medicine to every 1,022 persons in the United States. At the end of 1942 this figure had increased to 1 to 1,361, and by the end of 1943 it will be approximately 1 to 1,500. It is reported that England has 1 physician to approximately 230 persons in the armed forces and 1 physician to 2,700 in the ci-

vilian population. In this country the corresponding figures at the present time are approximately 1 to 160 for the armed forces and 1 to 1,400 for the civilian population. Germany is said to have approximately 1 physician to between 8,000 and 12,000 population. From this one can only conclude that the United States is relatively well off in terms of medical care both for the civilian population and for the armed forces.

As stated earlier, at the end of 1942 more than half of the practicing physicians under 45 years of age in this country were in the Army or Navy. By the end of 1943 practically all of those remaining who are physically fit and can be spared from civilian practice will be required to meet the minimum needs of the armed forces. This is the age group which is most active in medical practice and carries the biggest load of medical care. With them no longer available, the public is certain to feel a shortage of medical care. These shortages, however, need not be serious if the services of the remaining physicians are utilized intelligently and efficiently.

To do this it is important that patients do not call physicians unnecessarily and that, so far as possible, when they need a doctor they make appointments in advance so as to conserve the physician's time. It will be necessary also for physicians individually and as a group to plan to provide the public with essential medical services, whether they be in the office, the hospital or the home. Most physicians will need to add to their already long hours. Many who have completely or partially retired from practice will have to "carry on" once again. And all will have to share the responsibility for the medical services, including house calls, which normally would be rendered by the physicians who are now in service.

Medical Schools.—The students in medical schools are almost all members of the armed forces. Their education must be continued on an effective level. The lists of essential teachers submitted by medical schools indicate that some schools have already lost so many members of their faculties that it will be difficult, if not impossible, for them to conduct a satisfactory instructional program. Other schools have been more conservative and can release additional physicians in 1943 toward meeting the needs of the armed forces.

War Industries.—The continued expansion of war industries is creating an increasing demand for physicians. The Procurement and Assignment Service and the Council on Industrial Medicine of the American Medical Association are attempting to coöperate with the war industries in securing the physicians which they need. Efforts are being made, however, to secure physicians for these industries who are not eligible for military service and to replace as rapidly as possible the physicians in these industries who would be eligible for such service.

Public Health Services.—Most health departments are already functioning on skeleton staffs and are unable to release additional physicians for military service. In fact, some health departments are so urgently in need of trained personnel, that the United States Public Health Service is supplying such personnel on a "lease-lend" basis.

Hospitals.—The situation in the hospitals will become increasingly difficult. In order to conserve the time of physicians, there will be a tendency to hospitalize more patients. Medical school graduates who hold commissions in the Army and Navy will be granted a year, but only a year, of internship before being called to active duty. One result of this is that many of the large hospitals which previously had two-year internships are taking more first-year interns in order to "cover" their services. This can only mean that some hospitals will have less interns than normally.

Hospital residencies will be continued, but the number of residents who can be deferred from military service will be very limited. Consequently, hospitals will find it necessary to depend, almost entirely, upon residents who are not acceptable for military service.

Critical Shortage Areas.—It is estimated that approximately 6,000,000 people in this country have moved their homes as a result of the war. The provision of medical and health services to this group is one of the most important problems facing the medical profession and the Procurement and Assignment Service today. The principles and procedures for evaluating and meeting the needs of these groups were formulated in 1942, but most of the job still remains to be done.

The surveys which have been completed indicate that in many instances the urgent need is not for more physicians, or not only physicians, but rather for hospitals, nurses, or public health services. In a considerable number of areas the local medical societies in coöperation with public health departments and housing and welfare groups have been able to meet the needs for physicians either by having the doctors in the community or in neighboring communities give specific amounts of time to the shortage area or by inducing other physicians to move into the area. Reports from the states indicate that more than 900 physicians have taken positions in war industries or moved into "shortage areas" during the past year and that approximately two-thirds of these moves have been the result of efforts of State or local Procurement and Assignment Chairmen or Committees. Similar methods doubtlessly can and will meet these needs in many other communities.

Some of the "boom town" communities, on the other hand, need considerable numbers of physicians as well as hospital beds, nurses, and other health services. Although the ratio of 1 doctor to 1500 population has been utilized by the Procurement and Assignment Service for planning purposes as the over-all number of physicians required to provide essential medical services to the civilian population, in shortage areas, a ratio of 1 to 3,000 has been accepted as the coverage beyond which the situation would be considered critical.

The responsibility for formulating plans to meet these needs has been placed primarily upon the Procurement and Assignment Service and the state and local medical societies. Most of the residents of these areas are earning good incomes and should be able to support physicians on a private practice basis. If it is necessary in special situations to provide partial subsidy to a physician for a limited period of time to enable him to move into such an area and establish himself in practice, funds for such subsidy may be requested from the United States Public Health Service. In some areas pre-payment plans for medical services under the supervision of the state medical society are meeting the need. In rare instances it may be necessary to assign an officer of the United States Public Health Service to practice temporarily in the area. Such an assignment, however, will be made only as a last resort and upon the joint recommendation of the Procurement and Assignment Service and the United States Public Health Service.

In meeting these situations the medical profession is faced with a new responsibility. Medical societies have always been concerned with keeping their members abreast of new development and progress in medicine and with the maintenance of high standards of ethics and practice among their members. Never before have they had reason to feel responsibility for the availability or adequacy of medical care for the general population. The laws of supply and demand have largely taken care of that. Now, however, the war has given rise to a new problem of medical care which must be met. The physicians of this country are given the opportunity of meeting these needs in the way that one deems best. We sincerely hope and believe that they will be able to meet this challenge.

Conclusion

As the representative of the Directing Board of the Procurement and Assignment Service, I welcome the opportunity this occasion has provided to briefly summarize the major problems which confront each and everyone of us in the medical profession in the critical times remaining before our country can emerge victorious in the titanic struggle in which we are engaged. In meeting such responsibilities, the medical profession has always done its full share, and we are confident that, come what may, the physicians of this country can be depended upon to do their share and more in meeting their problems and responsibilities.

SURGEONS WILL SEW WOUNDS WITH NYLON SUTURES

Nylon sutures will be used by surgeons this year to sew war wounds, replacing Jap silk formerly used, E. I. du Pont de Nemours and Company announced.

Millions of feet of the plastic filament formerly produced for tennis racquets and fishing leaders are now being made for surgical sutures and large quantities are being shipped to United Nations' medical depots throughout the world.

Nylon filaments are solid strands, in contrast to braided silk sutures. It is claimed that germs from infected tissue are not absorbed and cannot travel through the nylon as through braid.

The synthetic is also inert, non-irritating and does not fray or splinter, the company reports.—*Science News Letter,* April 10, 1943.

COLLAPSE THERAPY IN TREATMENT OF PULMONARY TUBERCULOSIS

G. A. HEDBERG, M.D.

Nopeming, Minnesota

ONE need not dwell on the importance of collapse therapy in the treatment of pulmonary tuberculosis, as these measures have become well established throughout the country, particularly during the last ten years. The primary indications for collapse therapy are: (1) persistent cavity failing to close on bed rest; (2) progressive lesions failing to show evidence of retrogression on bed-rest regimen; and (3) in pulmonary lesions found in the adolescent individual. We at Nopeming, at least, have felt as a result of many years' observation that our conservative treatment of pulmonary tuberculosis in the teen-age group has been very unsatisfactory. We have become inclined to use collapse therapy, particularly pneumothorax, in all lesions in younger individuals showing definite signs of activity. The contraindications to this type of treatment are few and consist mainly of extreme toxicity with high febrile reactions, and such massive involvement that it is obvious that no sacrifice of any respiratory reserve may be made.

Pneumothorax is the ideal measure of collapse therapy; it is easy to induce; the collapse of the lung can be regulated without much difficulty; and even after the patient has left the sanatorium, the contact with his physician due to the necessity for refills is a great advantage in preventing a possible reactivation of his disease. Unfortunately, pneumothorax is satisfactory in only a minority of cases. Many times previous pleurisy has resulted in complete fusion of the pleura, which prevents induction of pneumothorax. More commonly, pleural reactions have resulted in adhesions which prevent collapse of the diseased lung, and the continuation of air refills in this type of case is not only useless from the standpoint of controlling the disease, but is very apt to be accompanied by complications of effusions and empyema.

In reviewing our experience in the induction of pneumothorax over the past two years (June 1, 1940, to June 1, 1942), we find that we attempted induction of pneumothorax in 158 individuals. Of this group, the staff considered that collapse was satisfactory in only thirty-nine (25 per cent). In forty-seven (30 per cent) pneumothorax was followed by an intrapleural pneumonolysis to sever adhesions. Twenty-four patients had pneumothoraces established, only to be abandoned as ineffective. This represents 15 per cent of the group. No space was established in 30 per cent (forty-eight cases). It is quite significant that this most ideal measure of collapse therapy when applied to the average run of patients admitted to a sanatorium is successful only in a minority of the cases. To the end of improving or substituting for this procedure, other methods of collapse therapy have been developed. At the present time we feel that the operation of intrapleural pneumonolysis, that is, severing of adhesions which prevent complete collapse, is our most valuable single procedure, and better than doubles the number of successful pneumothoraces. This operation can be done with very little reaction to the patient, and by proper supervision of the after-care, complications, primarily of fluid or bleeding, can be held to a minimum. During the past two years, eighty-four intrapleural pneumonolyses have been performed on sixty-one patients. I am not going into a complete description of this procedure except to say that very often it is safer to sever only part of the adhesions at one time, going in at a later date to complete the lysis when subsequent adhesions have been allowed to stretch more completely. Originally, we severed adhesions several months after induction of pneumothorax, but during the past two years we have usually performed this operation three or four weeks following induction of pneumothorax. By doing this, we feel we are preventing pleural effusions resulting from partial spontaneous tear of adhesions due to attempts at increasing collapse of the underlying lung. As we have become more familiar with this procedure, we have broadened its indication until we are quite willing to perform this operation in all cases in which adhesions interfere with collapse of the pathologic area regardless of whether the cavity has been closed or not.

From the Nopeming Sanatorium, Nopeming, Minnesota.
Read in the Symposium on Tuberculosis at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

I have gone into more complete discussion of this indication in an earlier paper.

The classic surgical collapse when pneumothorax has failed has always been thoracoplasty. This measure is well established in many programs of collapse therapy. During the past two years, we have performed thoracoplasties on twenty-five patients. This procedure, as you all know, has marked limitations in that the underlying pulmonary pathology must be fairly quiescent, of a fibroid type, and the contralateral lung must be quite adequate, as extensive rib resection throws the underlying lung entirely and permanently out of respiratory function. It is not necessary to dwell on the advantage of completing thoracoplasty in multiple stages; seventy-seven stages of thoracoplasty were used in completing the twenty-five cases mentioned. With care in handling the tissues during the operation and the patient preoperatively as well as after operation, this extensive surgical procedure is accompanied by surprisingly little shock to the patient.

Extrapleural pneumothorax has definitely established itself in our program of collapse therapy. We grant that the experience with this procedure varies greatly in different institutions and in reports by different chest surgeons. We have been extremely fortunate in our results and feel that this is a very satisfactory procedure when it can be carried out. I personally feel that one of the major reasons for its success in our hands is that it is done at the sanatorium and that the after-care which is extremely important is the responsibility of men thoroughly trained in the problems of pneumothorax. This procedure has distinct advantages. It can be carried out bilaterally, or in the presence of extensive collapse on the other side. Then too in most cases a minimum of good lung tissue is sacrificed in order to get a maximum collapse of the diseased lung. The operation itself is about as extensive and entails as much reaction, so far as the patient is concerned, as an upper-stage thoracoplasty.

My usual procedure in performing this operation is to remove a posterior portion of the third or fourth rib on the affected side, developing the lysis in the extrapleural space. In most cases a successful lysis can be carried out even though the x-ray appearance is that of a chronic fibroid lesion. However, if one finds that he cannot strip the lung, the procedure may be abandoned without having caused too much risk to the patient. The lysis is usually carried out to create a more than adequate collapse of the lung, and during the period of the next week or two the lung is allowed to partially re-expand in this region until it is felt that the most efficient type of collapse is being maintained. One must realize that hemothorax is always a complication of this operation and bloody effusions should be aspirated and irrigated vigorously until the space dries.

During the past two years we have performed this operation twenty-seven times on twenty-two patients. One patient had two-stage lysis on her right side and a single-stage operation on her left side. Four of these patients had bilateral pneumonolyses performed for the production of extrapleural pneumothorax. We have not been inclined to use paraffin pack as we feel that extrapleural pneumothorax is the preferable procedure in any case in which paraffin pack is indicated. The maintenance of collapse of the extrapleural pneumothorax is not particularly difficult when handled by experienced men. In many of these cases oleothorax has been added without complications.

Mainly to emphasize our declining respect for operations on the phrenic nerve, we performed only fourteen phrenic nerve operations, all except one of which were crushing of the phrenic nerve for temporary paralysis. We feel that the results of this procedure have always been questionable and that the damage to the respiratory mechanism, particularly if one is contemplating more extensive surgery at a later date, outweigh the advantage of this procedure. I have not attempted to discuss oleothorax and mention pneumoperitoneum only in passing to say that the results of this procedure have been very questionable in the opinion of our staff.

The intensification of "early diagnosis" campaigns and the widespread use of mass x-raying in war industry and armed service can result only in the discovery of more and more tuberculosis among the apparently healthy. It is obvious that a large proportion of these cases will be preclinical, in the old meaning of the term. Today we must modify our terminology to acknowledge that tuberculosis found early deserves and demands early treatment. Finding the disease in a stage devoid of symptoms imposes on us the obligation so to appraise cases and so to select treatment that development of symptoms will not occur and spread of tuberculosis will be prevented—*Tuberculosis Abstracts,* May, 1943.

CHEST CONDITIONS SIMULATING TUBERCULOSIS

E. R. CROW, M.D.

Ah-Gwah-Ching, Minnesota

IN the statistics covering admission to the Minnesota State Sanatorium during the past six calendar years there were 1,736 new admissions of which 103, or approximately 6 per cent, were found to be nontuberculous. Accurate diagnoses on all of the cases in this group could not be made, but clinical tuberculosis was ruled out by repeated Mantoux tests and by sputum smears and cultures. Special procedures such as bronchograms and bronchoscopy revealed bronchiectasis and tumor in some of them; serological examinations, clinical progress, x-ray studies and occasional autopsy reports all contributed assistance in the matter of establishing diagnoses other than tuberculosis.

I shall attempt to give a brief description of the significant diagnostic features that must be kept in mind if we are to avoid mistakes in differentiating some conditions which may be confused with pulmonary tuberculosis. It should be emphasized that the roentgenogram is not always the most reliable factor in making a diagnosis. Without a satisfactory history, some observation of the patient and laboratory studies, a single chest plate may be actually misleading unless read by an individual possessing more than average skill in interpretation.

Read in the Symposium on Tuberculosis at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

Acute Pneumonia

A roentgenogram taken of a 5-year-old child on admission (Fig. 1-a) showed a shadow of fairly even density occupying the greater portion of the right upper lung field. This could have represented a pure first infection tuberculosis but the rapid clearing after two weeks was inconsistent with that disease, although the Mantoux test in this child was positive. No examination of pharyngeal secretions for pneumococci was made but stomach washing cultures showed no tubercle bacilli. In typical lobar pneumonia, the x-ray density is usually homogeneous and corresponds in outline to the anatomical boundary of the lobe involved; often, however, the lobe may not be completely consolidated. Lateral views are important in middle lobe involvement. Haziness of the upper edge of a lower lobe consolidation seen on anteroposterior films can be due to the fact that the upper portion of the lobe tapers upward to a relatively thin segment and thus casts a lighter shadow than the base. Figure 1-b illustrates the amount of clearing and resolution that can occur in the short period of two weeks.

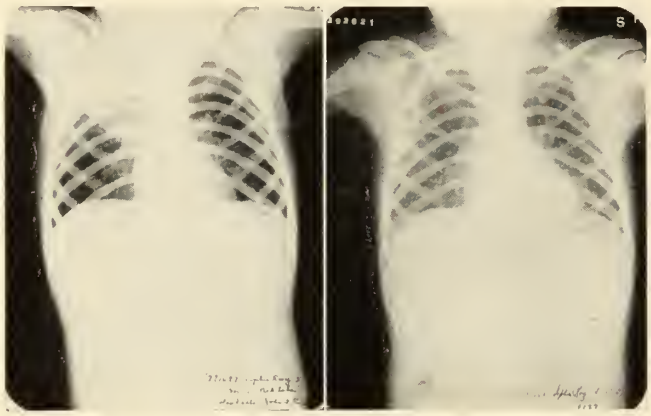

Fig. 1. (a) Pneumonia of right upper lobe. (b) After two weeks.

The second case is of a woman, aged forty-six, who had a history of loss of weight and strength over a period of five years. She had symptoms of hyperthyroidism, with subsequent

diagnosis of adenoma of right lobe and paralysis of the right vocal cord. She refused operation.

She had no cough, but complained of night sweats and was brought to the Sanatorium with

The x-ray diagnosis of the multiple irregular or fused areas of density produced by bronchopneumonia, is difficult and should not be attempted without noting the changes at frequent in-

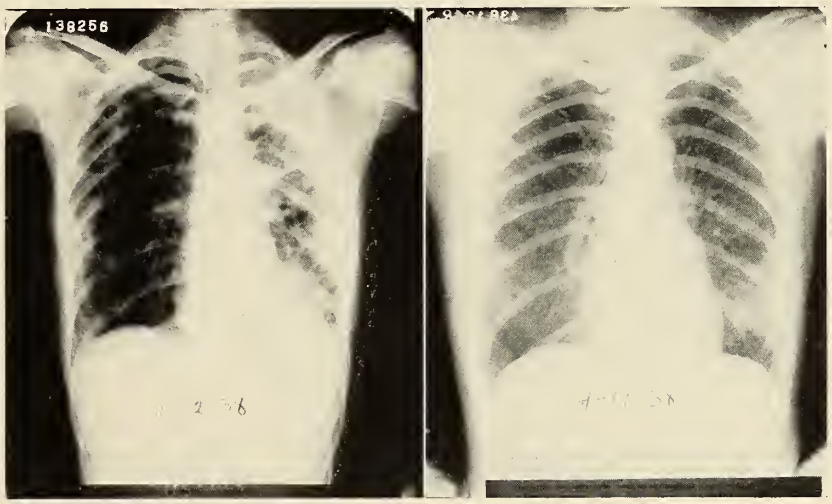

Fig. 2. (a) Atypical infiltration of entire left lung area simulating bronchopneumonia. (b) After three months.

suspected tuberculosis. Examination showed dullness and impaired resonance over the left upper lobe anteriorly (Fig. 2-a). Moist râles could be heard over this area. Tachycardia was present but the heart was otherwise negative.

Sputum examinations were negative, but blood smear showed a leukocyte count of 13,000 with 44 per cent eosinophiles. Urine and stool examination also proved negative for tubercle bacilli. Examinations of the stools for ova, parasites and typhoid bacilli proved negative.

After three months the eosinophile count had dropped to 11 per cent with clearing of the lung fields (Fig. 2-b). The sedimentation rate dropped from 26 mm. to 5 mm. and during this period she gained 35 pounds in weight. A short time later, the differential blood count was entirely normal.

Elson and Inglefinger recently reported two patients having a syndrome of atypical pneumonitis and eosinophilia associated with immune reactions to Brucella Abortus, in significant dilutions. The cases described showed positive skin tests also, although it is stated that this may have indicated only a previous brucellosis infection and not an active infection. They also cite several other sources dealing with the presence of an eosinophilia in connection with acute pulmonary infections.

tervals on serial films. Smears, sputum and cultures should always be obtained.

Silicosis

Figure 3 is that of a man forty-eight years of age who had a dry cough and dyspnea, becoming progressively worse during the period of a year. He stated that the symptoms followed an attack of pneumonia. During the time of his stay in the sanatorium he had a long series of negative sputum and culture reports. He died nine months after this picture was taken. The heart appears to be dilated on this film and he was found to have right ventricular dilatation on autopsy.

We see bilateral, evenly distributed areas of density equal in degree although irregular in shape due to their confluence and large numbers. There are no shadows of annular type suggestive of the cavities seen in tuberculosis. This is the nodular type of silicosis. Earlier stages of the condition, which is a chronic inflammatory reaction of the lungs to a nonbacterial agent, will demonstrate the principal x-ray diagnostic features which consist of:

1. Enlargement and increased density of hilar glands.

2. Bilateral lower and midlung areas of linear density radiating from the hilus which represent

perivascular and peribronchial lymphatics choked with phagocytes and, according to Cole, strands of collagen deposits around the bronchi and blood vessels radiating to the periphery.

Fig. 3. Silicosis involving both lungs.

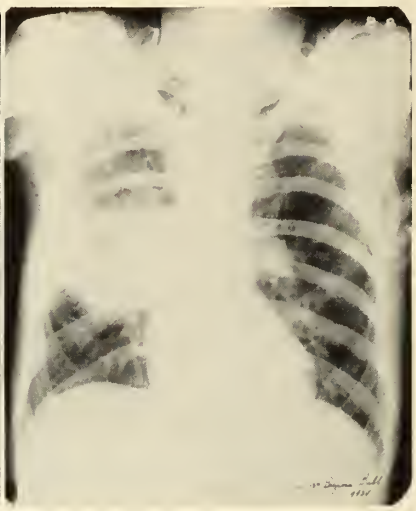

Fig. 4. Lung abscess involving right lung.

3. Silicotic nodules averaging 2 to 6 mm. in size, having the same distribution and said to consist of laminated collagen deposits. Involvement of the upper lung fields is usually found only in cases with a history of long exposure. Large numbers of silicotic nodules will produce the appearance of coalescence, as they grow together or become superimposed on the film.

Serial x-rays following hospitalization show no absorption of the nodules and little or no other change over long periods of time. Laboratory examinations are not of much value in diagnosis except to help rule out other conditions. Silicosis must be suspected and seriously considered in cases presenting a history of long exposure to silicate dust and having x-ray findings compatible with this disease, even though the presence of tuberculosis has already been established. Tuberculosis frequently complicates silicosis.

Pulmonary Abscess

Figure 4 is of a man fifty-five years of age with a significant history. Onset of symptoms began with an abscess of the tongue which ruptured spontaneously four months previous to x-ray. He complained of cough and expectoration of foul smelling sputum in large amounts—his illness being of the acute, stormy type. He was extremely toxic. Several sputum smears and cultures were negative for tubercle bacilli; the predominant organisms found were hemolytic streptococci. The Mantoux test was positive only in dilution of 1 to 100. Death occurred two months following admission and autopsy disclosed a large right lung abscess with a terminal bronchopneumonia of the lower lobes.

A pulmonary abscess is usually unilateral and found in the lower or midlung field. The history is that of aspiration of foreign bodies or infectious material, infarcts following thrombosis or peripheral suppurative lesions. Abscesses frequently occur following operations upon the upper respiratory tract. Modifications of the physical findings will be definite if the abscess is large, but none is pathognomonic of this condition.

X-ray will show the abscess shadow as a dense circumscribed area, thick-walled and usually containing fluid. The upper lung fields will be clear. A large, single tuberculous cavity in the lower lobe may be the principal source of confusion These are thin-walled, less frequently show a fluid level, and we expect to find tuberculous lesions elsewhere in the lung. If sputum is raised, the stained smear should show tubercle bacilli in large numbers. Sometimes the sputum is negative for tuberculosis and scant in quantity, from which we may infer that the bronchus is obstructed. With careful technique, bronchograms following lipiodol instillation are very helpful in demonstrating such obstruction. Not infrequent-

ly coughing will serve to loosen a bronchial plug, drainage will be established and tubercle bacilli will be found in subsequent smears.

Bronchoscopy may be indicated for diagnostic purposes, for aspiration of contents or for the removal of foreign bodies.

With good drainage, lung abscesses may diminish in size but thorocotomy with external drainage is sometimes necessary.

The evaluation of the Mantoux test here, as in other conditions, depends upon the age of the patient and other factors.

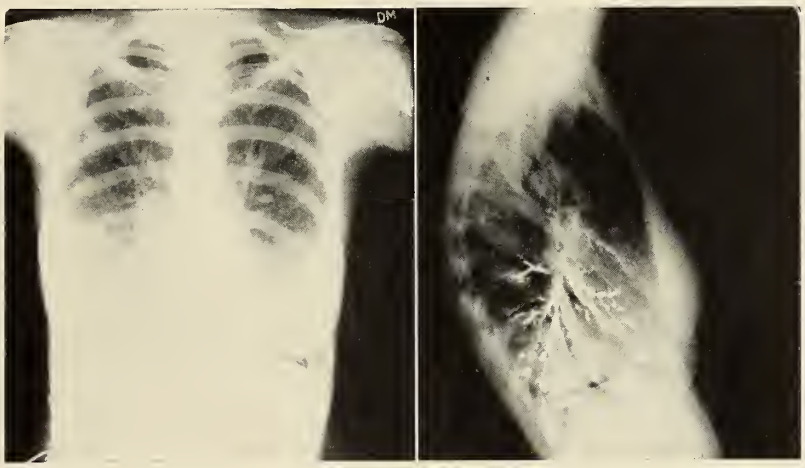

Fig. 5. (a) Antero-posterior view of patient with bilateral bronchiectasis. (b) Lateral view.

Bronchiectasis

In Figure 5 is shown the chest picture of a woman twenty-seven years of age before and after the instillation of lipiodol into the lower lobe bronchi. The history is that of a chronic cough with considerable expectoration over a period of twelve years, with loss of weight and debility. Occasionally the sputum was blood streaked. She was studied for a time and her sputum reports and cultures were consistently negative for tubercle bacilli. Her Mantoux test, however, was positive.

This is the typical picture of bronchiectasis, a condition characterized by dilatation of the bronchi. It may be associated with tuberculosis or with other pulmonary disease. It is a chronic and permanent structural change, and seems to depend on factors which tend to obstruct the drainage of the bronchus and is thus frequently seen in connection with intrapulmonary tumors, aneurysms, and enlarged hilus glands. Lower lobe bronchi are most commonly affected, and if upper lobe bronchi are involved, tuberculosis is more apt to be associated. Hemoptysis is a common symptom.

The bronchogram demonstrates the condition most readily, but the plain films often lead one to suspect bronchial dilatation. On the antero-posterior view in this case there will be seen fan-like linear densities radiating from the hilus downward to the lower lobes.

This film is likewise a good example of bilateral bronchiectasis, also apparently nontuberculous. The patient was a fifteen-year-old boy with a negative Mantoux test with 1 to 100 dilution and a negative guinea pig culture.

The history of these patients is that of a chronic cough with copious expectoration, recurring episodes of acute respiratory infections. It should be kept in mind that x-ray films of these patients may also show areas of atelectasis, abscess, evidence of bronchial tumor, abnormalities of the cardiac shadow or foreign bodies.

Carcinoma of the Lung

Primary bronchogenic carcinoma or secondary metastatic involvement of the lung may simulate tuberculosis. The same may be said of benign tumors. Cough, pain, sputum production, hemoptysis and constitutional symptoms are usually present. One of the principal features of early

bronchogenic tumors is partial or complete bronchial obstruction producing wheezing, baying type of cough and dyspnea. In carcinoma, pain and dyspnea are more prominent symptoms than in tuberculosis. Dyspnea is not distressing in tuberculosis except in the advanced stages. Tuberculosis, moreover, is a disease of youth but 80 per cent of carcinomata of the lung occurs after forty years of age.

The x-ray is of great value in diagnosis. While both tuberculosis and carcinoma show a predilection for the upper lobes, carcinoma usually spares the apices and originates in the hilus. Partial or complete atelectasis of an area without lesions suspicious of tuberculosis elsewhere in the lung is suggestive of carcinoma. Such areas, in fact, are usually the first x-ray evidence of tumor, and are due to obstruction of the bronchus of this area. Sometimes a peripheral zone of emphysema may be seen.

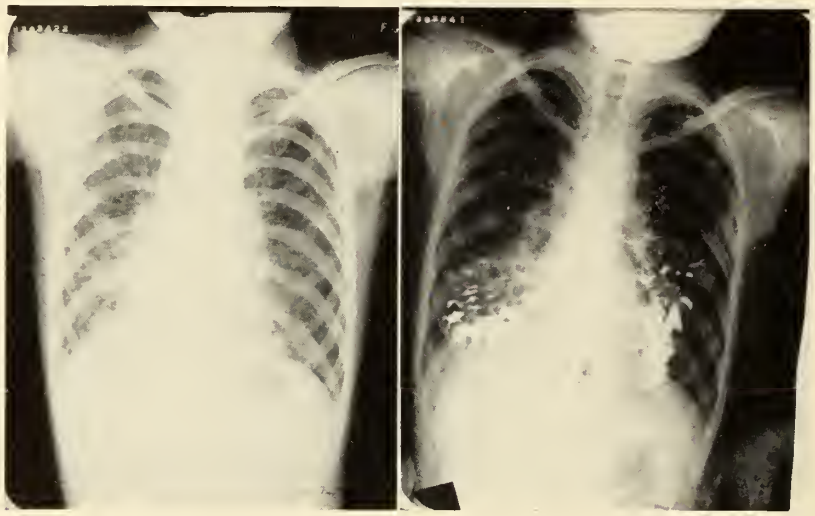

Fig. 6. (a) Flat radiograph of a patient with bilateral bronchiectasis. (b) Film after lipiodol injection.

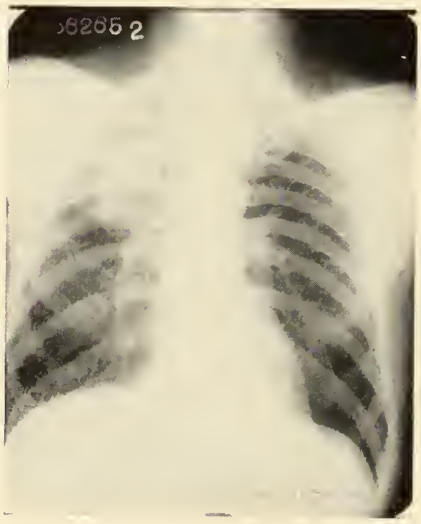

Fig. 7. Radiograph taken one year before death showing an atelectatic area in the right upper lobe with a surrounding area of emphysema. The right apex is apparently clear.

In making a diagnosis the sputum findings are of great importance. Bronchography may be useful in demonstrating the location and extent of bronchial occlusion. Sometimes the tumor may be outlined by the contrast medium. Bronchiectasis may develop in the portion of the lung distal to the point of obstruction. Likewise effusion may appear.

Bronchoscopy may make the diagnosis if the tumor can be reached and a biopsy obtained. Sometimes artificial pneumothorax is resorted to in order to displace the lung and thus bring the upper lobe bronchus within reach of the bronchoscope. The differential diagnosis then may be summed up as follows: History, sputum studies, x-ray appearance, bronchography, and bronchoscopy.

Without attempting to discuss them here, mention should be made of several other chest conditions which can cause confusion in diagnosis. Such are congenital cysts of the lung, ecchinococcus cysts, the mycotic group, actinomycosis, blastomycosis, and also sarcomatous tumors.

Chronic passive congestion and postoperative atelectasis may also occasion difficulty in certain

cases, although a careful history, physical examination and x-ray studies will usually identify them.

Figure 7 is a roentgenogram of a man sixty-

chogenic carcinoma was made. He was given deep x-ray therapy.

Figure 8-A is a film of a woman originally diagnosed as miliary tuberculosis, and shows nod-

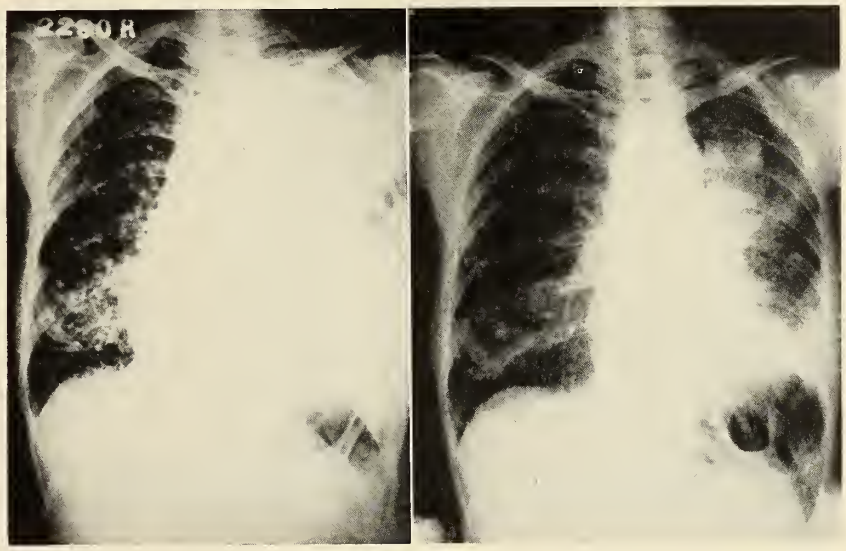

Fig. 8. (a) Left bronchogenic carcinoma followed by miliary type of metastasis in right lung. (b) Following aspiration of fluid from left pleural cavity.

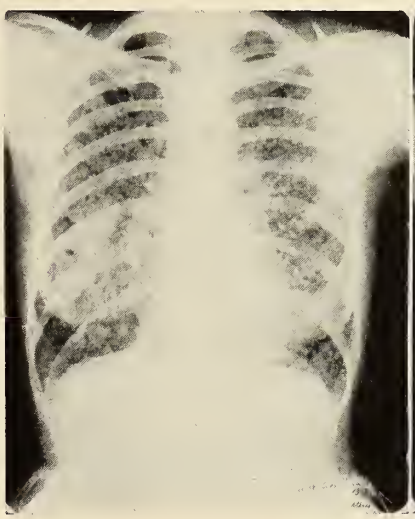

Fig. 9. Discrete mottling of uniform distribution of both lungs without cavity formation.

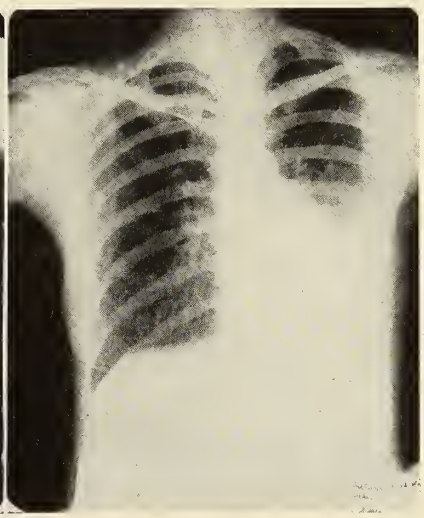

Fig. 10. Atelectasis of lower left lung field caused by benign bronchial tumor.

one, well until a few months previous to examination. He had had an influenzal attack, followed by cough, expectoration, and moderate hemoptysis. Several sputum specimens were negative for tubercle bacilli. Bronchoscopic examination was done, but the upper lobe bronchus could not be visualized. This man was sent to the University Hospital and a diagnosis of bron-

ular areas of density in the right lung, and a pleural effusion on the left side. The densities, while evenly distributed, are larger than the type seen in miliary tuberculosis. In addition, the patient had no fever, no dyspnea, and was not toxic.

Figure 8-b was taken following aspiration of the fluid on the left and introduction of a small

amount of air. The detail of the left lung is now clear and shows densities similar to those on the right. In addition, an area of atelectasis is seen in the left lower lobe, indicative of obstruction of the bronchus. Bronchoscopy revealed a tumor in the left lower lobe bronchus. Diagnosis: Bronchogenic carcinoma with generalized metastases throughout both lungs.

Figure 9 is a roentgenogram of a woman with a history of dyspnea and expectoration for two months prior to the taking of the film. The Mantoux test, several sputum specimens and one culture were negative. She had had a gynecologic operation (hysterectomy ?) some years before.

Partial autopsy showed carcinoma cells and filling of alveoli with a mucinous secretion, believed to be metastatic from the ovary.

Figure 10 is a roentgenogram of a young girl with a history of cough and dyspnea. X-ray shows atelectasis of the lower left lung field, the other areas being clear. Bronchoscopy demonstrated a small pedunculated tumor obstructing the left lower lobe bronchus. This was excised and the atelectatic area later re-expanded. The patient was still living and well two years later.

Figure 11a is the roentgenogram of a man of forty taken before he came to the sanatorium. He had had an acute illness three years before, diagnosed pneumonia. On admission, however, he had no cough, fever, nor night sweats. Sputum examinations were negative at all times. Blood specimens repeated several times were reported 4+ Kline and Kolmer. He was observed at the Minnesota State Sanatorium over a period of fifteen months during which time he received intensive antiluetic therapy. At the end of this time his lungs had cleared on x-ray examination as shown (Fig. 11-b). We believe a presumptive diagnosis of luetic pulmonary involvement is justified in this case.

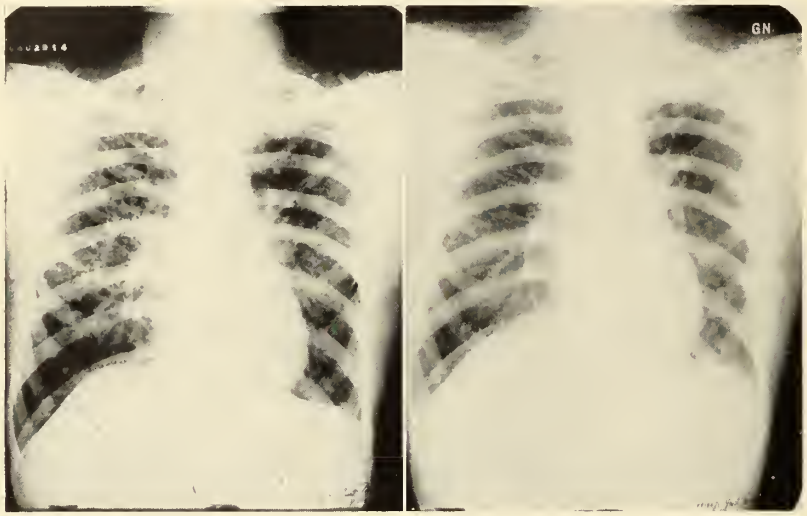

Fig. 11. (a) Diffuse increase in lung design in a patient with positive blood Wassermann. (b) Same patient following luetic treatment.

THE TUBERCULOUS WORKER IN WAR INDUSTRIES

The successfully treated part-time or full-time tuberculous worker can contribute to the manning of the war industries with great benefit to the nation and to the worker himself. A risk is present, but if workers are chosen on a sound medical basis, the risk is not great and is worth taking particularly in the present emergency. Plans must be made also for the future tuberculous service men and civilian war workers. The expansion of the facilities for training and placement of tuberculous workers is necessary. The establishment of workshops for industrial convalescence and perhaps colonies for chronic patients is called for.—Louis E. Siltzbach, M.D., *Milbank Memorial Fund Quarterly*, January, 1943.

NATURALLY ACQUIRED TUBERCULOSIS IN HETEROLOGIC HOSTS

WILLIAM H. FELDMAN, D.V.M., M.S.
Rochester, Minnesota

WITH certain reservations tuberculosis may be said to be a ubiquitous disease. Not only is it practically worldwide in its geographic distribution, but of great interest is the occurrence of the disease in a wide variety of species. Natural occurrence of the disease in most of the warm-blooded mammals and fowls and in such cold-blooded animals as alligators, iguanas, turtles, frogs, fish and snakes makes it evident that few if any species of animals have an absolute resistance to the disease. Individual resistance or susceptibility to tuberculous infections varies within wide limits and this fact should be taken into consideration before one draws conclusions as to whether a given species is susceptible to infection with one or more of the several bacterial types of the causative organism.

The Avian Tubercle Bacillus

Tuberculosis of the lower animals is of importance for several reasons. Few indeed are the bacterial diseases that provide the student of comparative pathology such phylogenetic diversity as tuberculosis. Such studies furnish information that makes the fundamental pathologic characteristics of the disease in all species more understandable. The existence of many different recognizable types of tubercle bacilli and the fact that many lack host specificity and are capable of inducing slight to severe tuberculous disease in heterologous hosts complicate tremendously the problem of tuberculosis control. For example, the natural host of avian tubercle bacilli is the chicken; yet in addition to a marked pathogenicity for other barnyard fowl and many species of wild birds, avian tubercle bacilli are responsible for serious losses in swine. Avian tubercle bacilli also affect sheep and occasionally cattle.

The possibility that avian tubercle bacilli may be pathogenic for human beings has interested many clinicians as well as many laboratorians. The widespread distribution of avian tuberculosis over most of the northern hemisphere, the excessive numbers of bacilli present in the lesions of chickens and the frequent presence of intestinal lesions that discharge large numbers of bacilli that are excreted with the fecal discharges all constitute abundant opportunities for the transmission of the disease to uninfected susceptible hosts. Fortunately, human beings appear to have a high resistance to tubercle bacilli of the avian type and as a consequence few authentic cases of avian tuberculosis infection in human beings are on record. It is true that the literature contains many alleged cases in which the infective agent was stated to be avian tubercle bacilli, but when the reports are scrutinized carefully, acceptable or convincing proof necessary to substantiate a diagnosis of avian tuberculosis infections is lacking in most instances.* In all the literature pertaining to tuberculosis of human beings there are probably less than twenty cases in which it is reasonably certain that the infective agent was the avian tubercle bacillus.

The avian tubercle bacillus also has been considered of etiologic significance in Hodgkin's disease. Although it cannot be said that the problem has been studied exhaustively, the evidence in support of a causative relationship of avian tubercle bacilli and Hodgkin's disease is far from convincing.

The Bovine Tubercle Bacillus

The organism of bovine tuberculosis also may produce disease in swine, dogs and cats. Although most birds are highly resistant to bovine tubercle bacilli, canaries and parrots may be affected. Of great importance, however, is the fact that human beings are susceptible to bovine tubercle bacilli. This well-established fact has been reëmphasized during the past decade by the demonstration in certain European countries, especially England, Scotland and Denmark, of several hundred cases of pulmonary tuberculosis in human beings due to the bovine type of infection. Heretofore the intra-abdominal tissues and the bones and joints were considered the usual situations for infection of human beings with bovine tubercle bacilli, but we must now

Read in Symposium on Tuberculosis at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 1, 1942.

*A complete review of the question of avian tuberculosis infections in human beings will be found in my monograph.

recognize that the bovine type of the organism is fully capable of producing the more serious pulmonary form of the disease.

The Human Tubercle Bacillus

The human type of the tubercle bacillus is also capable of producing serious tuberculous disease in heterologous hosts. However, with the exception of parrots, human tubercle bacilli are incapable of producing a progressive, serious infection in birds. Incidentally, parrots appear to be more susceptible to bovine and human tubercle bacilli than to avian tubercle bacilli. Swine also may become infected with human tubercle bacilli. In a series of garbage-fed hogs studied a few years ago I found that 25 per cent of the animals from which tubercle bacilli were obtained were harboring tubercle bacilli of the human type. The public health implications of such findings are obvious. Although the pathogenicity for cattle of human tubercle bacilli is slight, a few cases in which this organism was responsible for tuberculosis in cattle have been reported. Recently material from one such case was studied in my laboratory. The animal was an adult bovine that had been shipped for slaughter from Canada to South Saint Paul, Minnesota. At necropsy sufficient tuberculosis was found to require the condemnation of the carcass. Tubercle bacilli that were proved eventually by animal pathogenicity tests to be of the human type were obtained from the lesions in the lung and one of the bronchial lymph nodes.

A résumé of the evidence available suggests that human tubercle bacilli are rarely responsible for lesions of naturally acquired tuberculosis of cattle. The infrequency of this type of infection and the character and anatomic distribution of the morbid changes make it unlikely that the human type of tuberculous infection in cattle may be transmitted from one animal to another. In other words, once the disease is established in a bovine animal, it usually remains localized and the lesions show a marked tendency to heal or to become quiescent.

There is, however, a phase of the problem that is worthy of brief comment. This is the possibility of cattle becoming sensitized to mammalian tuberculin as a consequence of contact with human tubercle bacilli derived from persons affected with pulmonary tuberculosis. Several workers have investigated this problem and have assembled a sufficient amount of presumptive evidence to substantiate the conclusions that cattle, exposed to infective material from human beings affected with human tubercle bacilli, may become sufficiently sensitized to mammalian tuberculin to elicit a diagnostic reaction to the intracutaneous tuberculin test. The reports reviewed seem to indicate that after the source of the human tubercle bacilli has been removed, the animals gradually lose their sensitivity to tuberculin. It is obvious, therefore, that persons suffering from active pulmonary tuberculosis should be excluded from premises frequented by cattle—not especially because the disease may be transmitted to the cattle but because of the greater possibility of sensitizing the animals to tuberculin that may be used in subsequent diagnostic tests.

The question of whether a cow harboring human tubercle bacilli as a consequence of natural exposure will eliminate tubercle bacilli with the milk has been studied rather comprehensively by Hinderson and by Nielsen and Plum and the results failed to reveal a single instance in which this occurred.

The human type of the organism also affects dogs and a large number of such cases have been recorded. Since in the majority of cases the lungs are affected it is evident that the tuberculous dog may well become a menace to the health of human beings and especially to children who frequently fondle their canine pets. Dogs are also susceptible to infection with bovine tubercle bacilli, although most of the cases of tuberculosis of dogs that have been reported have been due to the human type of the organism. This is not because dogs are less resistant to human tubercle bacilli than to the bovine type of the organism. The explanation is that there exist more opportunities for exposure to the human type of the bacillus. Of some interest to the pathologist is the fact that the morbid changes in tuberculosis of dogs are without giant cells of the Langhans type and that calcification rarely occurs. Dogs have a formidable resistance to avian tubercle bacilli; only one authenticated case is on record.

But few cases of tuberculosis in cats have been recorded. Unlike the dog, the cat is not equally susceptible to human and bovine types of tubercle bacilli; of the fifty-six cases reviewed recently by Lovell and White all except four were of the bovine type. The evidence necessary to identify the causative agent positively in the four cases

which were listed as of the human type was inadequate in some instances. The rarity of tuberculosis in the cat due to human tubercle bacilli seems to be established.

Comment

From this brief résumé the wide diversity of tuberculous disease is evident. The ability of all three types of tubercle bacilli responsible for tuberculosis in warm-blooded animals to infect, frequently seriously, heterologous hosts should be recognized more generally. If this fact is fully understood and its importance amply appreciated, the necessity of a comprehensive plan of control and eradication of tuberculosis becomes evident. To eliminate the tuberculosis in one species and ignore the disease in others is not likely to solve the larger problem. Ideally our goal should be the elimination of tuberculosis from all species. Until this is done it is possible for the disease to exist in heterologous hosts in which the presence of tubercle bacilli constitutes a potential source of new infections, perhaps in natural hosts.

Notable progress has been and is being made in subduing the disease in all the natural hosts except the chicken. We have in our possession the necessary knowledge literally to eradicate human, bovine and avian tuberculosis. However, to accomplish the task will require aggressive and noncompromising action. Gains made must be vigilantly guarded and constantly expanded. An attitude of complacency or one in which past achievements are given precedence over the importance of the task yet to be done will defeat any plans of attack, no matter how adequate they may be. The tubercle bacillus ranks high as an enemy of man and of the lower animals and should be dealt with accordingly. It can never be subdued and made a decent member of society by the terms of any armistice. Attack rather than defense should be our watchword.

DIAGNOSIS OF EARLY TUBERCULOSIS AMONG UNIVERSITY STUDENTS

RUTH E. BOYNTON, M.D.

Minneapolis, Minnesota

THE early diagnosis of tuberculosis in any group will be achieved only when some program is adopted in which it is possible to make a diagnosis before the disease has developed to a stage where symptoms are present. This ideal can be reached in the population at large when two things are accomplished: (1) when the public has been educated to the point where they will go to their doctors annually for periodic health examinations; and (2) when every physician will include a tuberculin test and x-ray examination of all reactors as a part of such a periodic examination. It undoubtedly will take many years before the Utopia just suggested will arrive. The practicality of such a program in the early detection of tuberculosis, however, has been amply proven in tuberculosis case-finding programs which have been carried out among all age groups in many localities.

In our colleges and universities an ideal opportunity exists to diagnose tuberculosis in its presymptomatic state. Medical examinations required at entrance to the university and subsequent periodic health examinations during the four years in college afford an unusual opportunity to find tuberculosis in an age group in which the disease is known to be prevalent.

At the University of Minnesota over a period of over twenty years a program has been carried out in which we have endeavored to detect the presence of tuberculosis before it has reached a symptom-producing stage. On entering the University every student is given a complete physical examination. This examination includes the

Mantoux tuberculin test and a chest x-ray of all who react to tuberculin. That early tuberculosis will be missed unless the medical examination includes tuberculin testing and a chest x-ray of reactors is evident to anyone who has examined large groups of people. In our institution a study which was made of re-infection type of tuberculosis found in University students over a five-year period showed that only 10 per cent of the minimal cases had physical signs suggestive of disease on examination of the chest, and only 24 per cent of the moderately advanced cases. Had we been depending on the physical examination of the chest alone, over three-fourths of the cases of active re-infection type of tuberculosis would have been missed.

In the year 1940-41 over 4,600 University students were given a complete medical examination at the time of entering the University. For the tuberculin test Koch's old tuberculin was used in two doses. The initial dose contained one-tenth of a milligram of old tuberculin; and the second dose, given to all who were negative to the first test, one milligram of old tuberculin. Twenty-seven and nine-tenths per cent of the men and 29.6 per cent of the women students reacted to tuberculin. Slightly over one-fourth of the students entering the University then are potential cases of clinical tuberculosis at the time they come to school.

The importance of using the two-dose method of tuberculin testing is shown by the fact that approximately 13 per cent of those students who were negative to one-tenth of a milligram of old tuberculin showed a positive reaction when the test with the one-milligram dose was used.

While only a small proportion of students reacting to tuberculin are found to have any evidence of infection in the lungs by x-ray examination, it should always be kept in mind that a person who has a positive tuberculin test undoubtedly has a focus somewhere in the body, and the fact that the chest x-ray is negative should not lull one into a false sense of security that such an individual needs no further observation. Our experience has shown that not infrequently tuberculosis in some part of the body other than the lungs may appear at a later date. It is our practice to refer all tuberculin-positive students to our tuberculosis clinic, which has been under the direction of Dr. J. A. Myers for more than twenty years, where they may be kept under observation throughout their residence in the University.

In the same year of 1940-41 through the routine medical examination of students, either on entrance or at the time of a subsequent periodic examination of students who had been in school, forty-five cases of re-infection type of tuberculosis were found. Of this forty-five, fifteen or one-third were diagnosed as clinically active cases, twenty-one as clinically inactive, and there were nine cases in which the activity was undetermined. During the same year there were thirty cases of previously diagnosed re-infection type of tuberculosis who were back in college, making a total of seventy-five cases under observation during this one school year.

TABLE III. INCIDENCE OF RE-INFECTION TUBERCULOSIS

	Men	No. per 1,000	Women	No. per 1,000	Total	No. per 1,000
Total registration 5-year period	43,037		26,658		69,675	
Total cases of re-infection tuberculosis	56	1.3	70	2.62	126	1.8
Arrested	11	0.25	20	0.75	31	0.44
Minimal	34	0.79	38	1.42	72	1.0
Moderately advanced	10	0.23	11	0.41	21	0.3
Far advanced	1	0.023	1	0.037	2	0.028

its early stage possible, is shown in Table III. This presents the cases of re-infection type of tuberculosis found in University of Minnesota students over a five-year period. Of ninety-five cases of active tuberculosis during this period, seventy-two were classified as minimal, twenty-one as moderately advanced, and only two as far advanced. Since we know that only 10 per cent of the minimal cases were found to have abnormal chest findings on physical examination alone, it is obvious that without the routine use of the tuberculin test and the chest film over sixty of these cases of minimal tuberculosis would have been missed.

Evidence that the periodic health examination and not the office visit or examination when hospitalized is the most productive time to detect tuberculosis in its early stages is presented in Table IV. At the University of Minnesota over a five-year period there were 126 new cases of tuberculosis diagnosed. Of these, 56.4 per cent were found at the time of the routine entrance examination and 32.5 per cent at the time of the routine periodic health examination. In other words, 89 per cent of the cases of re-infection type of tuberculosis found in students during this period were found as a result of a routine health examination and not because the students were seeking medical aid because of symptoms.

TABLE IV. RE-INFECTION TUBERCULOSIS

First Discovered In:	Arrested		Minimal		Moderately Advanced		Far Advanced		All Types	
	Total	%	Total	%	Total	%	Total	%	Total	%

Total	31	100	72	100.0	21	100.0	2	100	126	100.0

In the clinical cases found to be active the University feels its responsibility is to aid these students in obtaining proper treatment by referring them home to their private physicians. Those cases of inactive tuberculosis are kept under very close observation in the Health Service. They must report regularly for examinations, must have the gastric contents examined to determine whether tubercle bacilli are present, must have frequent x-ray examinations of the chest so that we may be assured that individuals with active tuberculosis are not living in the University community. Likewise those in whom at the time of the initial examination the activity of the disease cannot be determined are studied frequently and carefully until assurance can be given that active disease does not exist.

That routine physical examinations including specific diagnostic measures for the detection of tuberculosis will make diagnosis of the disease in

The following case histories will illustrate some of the points which I have made. (Lantern slides were presented.)

Case 1.—This case is that of a young man who entered the University of Minnesota in 1931. At his entrance examination he was negative to one-tenth of a milligram of old tuberculin but showed a reaction to

the one-milligram dose. An x-ray of the chest taken at that time was reported as negative. Reëxamination of this radiograph later showed that there apparently was a shadow in the left lung near the periphery about the level of the fifth interspace anteriorly which proved to be a primary tuberculous focus in the pneumonic stage. Because of his positive tuberculin reaction, this student had chest x-rays annually for a period of eight years. He entered the Medical School and thus was under observation for this length of time. Until 1935 there was little change in the appearance of the chest. The radiograph taken in 1937 showed definite evidence of calcification at the site of the previous shadow and in the left hilus region, which was interpreted as a Ghon's tubercle, and some calcification of the mediastinal glands. This is a case in which the reaction to the first infection with tuberculosis was seen very early, in which by periodic chest examination it was possible to watch the process go on to calcification and the development of the characteristic Ghon tubercle and calcification of the hilar glands.

Case 2.—This case illustrates the importance of considering a positive tuberculin reaction as important regardless of whether the chest shows any evidence of infection in that locality. This is an older student, a woman forty years of age, who entered the University in the fall of 1939. She gave a history of having had a positive tuberculin reaction before entering the University. An x-ray of her chest showed calcium deposits in the right hilus region but no other evidence of disease in the lungs. The history revealed, however, that she had had extensive tuberculosis of the pelvic organs with a tuberculous peritonitis two years previously for which she had had surgical treatment elsewhere. A report from the clinic where she was treated confirmed this diagnosis.

Case 3.—This case is that of a Negro girl who entered the University in September of 1939 as a senior. She was twenty-two years old. In the history she stated that a grandmother had had tuberculosis, but gave no history of contact. She was a reactor to tuberculin at the time of her examination, and the routine chest x-ray was taken. This radiograph made on November 29, 1939, was clear except for evidence of a small calcium deposit in the right lung at the level of the fourth interspace anteriorly. She was referred to our chest clinic and was advised to have another radiograph of the chest made in one year.

In February, 1940, three months after the first radiograph, the patient developed what apparently was a mild upper respiratory infection. This persisted for ten days with an elevation of temperature which did not exceed 99.6 degrees during this period but with a persistent cough. The physical examination of the chest was essentially negative. However, because she was living in a rooming-house and this so-called "cold" had persisted, she was admitted to the students' infirmary. A radiograph made of the chest on March 2, 1940, the day of admission, showed evidence of disease in the left lung which proved to be a tuberculous pneumonia. Tubercle bacilli were present in the sputum on several examinations. This student was sent to her home state for sanatorium care.

Case 4.—This case is that of a student who entered the University in the fall of 1939, and who reacted to tuberculin with one-tenth of a milligram of old tuberculin. He gave a history of having been exposed to tuberculosis, his father having died of the disease, and his mother having had an infection. The routine film made on October 24, 1939, showed no evidence of disease. Because of the history of immediate family exposure, this student was advised to have another film made in six months. This was done and the radiograph made in May of 1940 again showed no evidence of pathology. On returning to school the next fall another radiograph of the chest was requested and made on November 13, 1940, just six months after the last radiograph. This time there was definite evidence of a process undoubtedly tuberculous which was present in the right apex and extended down to the second rib. Several small areas of increased density were thought to represent small cavities. A review of the film of May, 1940, showed some increased density in the right apex which could easily have been and was misinterpreted for a soft tissue shadow. Undoubtedly this represented the early tuberculous process at that time. This case illustrates exceptionally well, I believe, the importance of repeated periodic examinations of the positive tuberculin reactor, even though the initial radiograph shows no evidence of pathology, and particularly when there is a definite known history of intimate exposure.

Case 5.—This case is that of a student eighteen years old who entered the University in September, 1939. He reacted to one-tenth of a milligram of tuberculin at the time of this examination. A radiograph of the chest taken on November 4, 1939, showed no evidence of pathology. Another radiograph taken in November, 1940, also showed no evidence of disease. In January, 1941, the student reported to the Health Service complaining of a pain in the right side of the chest which had been present for forty-eight hours. He had had a mild upper respiratory infection for a few days but had had no cough or fever. The physical examination of the chest at that time revealed no evidence of friction rub nor râles. He was fluoroscoped and a shadow was present in the right apex, and a film of the chest was ordered. This radiograph showed an infiltrating process extending from the apex down to the fifth rib anteriorly on the right side with a cavity under the clavicle at the end of the first rib and also a cavity at the end of the fourth rib anteriorly. The left lung was negative. Tubercle bacilli were present in the sputum. This again is a case in which the student had had a negative radiograph two months prior to the diagnosis of a rather extensive tuberculous process and emphasizes again the importance of keeping under careful observation the positive reactors.

Case 6.—This case is that of a student who entered the School of Nursing in 1930 at which time she reacted

positively to one-tenth of a milligram of old tuberculin. An x-ray of the chest was negative. During the time that she was in the School of Nursing she had annual radiographs made of the chest which until 1934 showed no evidence of any disease. The routine radiograph made in October, 1935, showed evidence of a tuberculous process with cavity formation in the left lung. She was having no symptoms at the time this radiograph was made.

Evidence has been presented to show the importance of keeping under observation the reactors to tuberculin whether the chest radiograph shows evidence of disease or not. In some cases the tuberculous process may be elsewhere in the body and may be missed unless one keeps in mind this possibility.

Our experience with a tuberculosis case-finding program at the University of Minnesota, as illustrated by the cases presented, has made us firmly believe that if tuberculosis is to be found in its early stages, a specific effort must be made to detect the disease. In our opinion one of the most effective means of doing this is through the periodic health examination which must include the tuberculin test and the x-ray reactors. Eighty-nine per cent of the cases diagnosed among University students were found as the result of such routine examinations.

HOW A COUNTY CAN BE ACCREDITED FOR TUBERCULOSIS CONTROL

S. A. SLATER, M.D.
Superintendent and Medical Director Southwestern Minnesota Sanatorium
Worthington, Minnesota

TWO outstanding undertakings sponsored by the Minnesota State Medical Association have been initiated since our last annual meeting. These are the Meeker County demonstration for the control and eradication of tuberculosis and the plan for accrediting counties meeting certain requirements in the control of tuberculosis. Dr. Danielson has told you of the Meeker County demonstration, and I will attempt to explain how a county can be accredited and what it means. These two undertakings have caused more interest, not only in this state, but in others, in tuberculosis control, than anything I can recall in the past twenty years. I am glad the State Medical Society is primarily responsible for both of these undertakings. It shows that the medical profession is deeply interested in the fight against tuberculosis. This unusual interest will do much to insure its success. Again Minnesota is the leader in the fight against tuberculosis. In 1910 the death rate was 110 per hundred thousand; by 1940 it had fallen to 27.7 per hundred thousand. In a few counties of the state over a five-year period it had fallen to an average of less than 10 per hundred thousand. The results are most encouraging but the fight has not been won and we must not lessen our effort until victory is complete. Even the counties with the extremely low death rates will experience an early rise if they do not continue on the job, looking for the enemy and attacking as soon as discovered.

The requirements for a county to become eligible for accreditation is to have an average death rate over the previous five years of less than 10 per hundred thousand. At least 75 per cent of the graduating high school class of the county must be tested with 0.1 mg. of old tuberculin or the equivalent with not more than 15 per cent reacting positively to the test. There are only four counties in the state at the present time showing a death rate of less than 10 per hundred thousand. There are quite a number of counties with a death rate of from 10 to 15 per hundred thousand, and others ranging from this figure to a high of 68 per hundred thousand in one county. With an average death rate for the state at present of 27.2 per hundred thousand, and an increased effort and interest on the part of every physician, the entire state should be accredited in a few years. Lincoln County with a death rate of 5.5 per hundred thousand for the five years previous to 1941 was the first county in the world to become accredited for the control of human tuberculosis. This county received its certificate of accreditation December 11, 1941. Olmsted County was second and received its certificate May 22, 1942.

Read in the Symposium on Tuberculosis at the annual meeting of the Minnesota State Medical Association, Duluth, Minn., July 1, 1942.

Murray County will be the third and will receive its certificate some time this fall. If the death rate continues to fall in Minnesota, several counties of the state should be accredited each year. Will this be accomplished? The answer lies with the physicians of the state. A successful fight against tuberculosis depends more on the interest of the general practitioner than any other single factor. Experience has shown that when the physicians are actively interested in the fight against tuberculosis, that county shows a proportionately low death rate. Since some of the counties are now becoming accredited, other counties are asking the question, how can they do likewise? There are many things entering into a successful fight against tuberculosis. It is largely a coöperative effort and every means possible at our command should be used. The physician has to be aroused and the public has to be educated. Both must realize that most cases of tuberculosis are well advanced before symptoms appear sufficient to cause a patient to consult a physician. The only way to find the early case is to look for it. When everyone realizes this and acts accordingly much will be accomplished. Every means possible should be exerted to find all open cases of tuberculosis as early as possible. When found they should be removed immediately to an institution where they will have the best chance to recover and the public will be protected. The family and contacts of open cases of tuberculosis should be examined to discover individuals with early tuberculosis, while they have a good chance to recover and before they have endangered others. All school boards should require the teachers and other employes of the school to present medical proof that they are free of tuberculosis. It has been shown that a single teacher who was an open case of tuberculosis infected at least 80 per cent of her pupils. An active tuberculin testing campaign of the school children is of considerable value. Probably the best results can be obtained by testing the first-year pupils and the seniors each year rather than testing all pupils infrequently. Such a program keeps the interest in tuberculosis control alive and yet limits the number of individuals tested so that adequate follow-up work can be done on the contacts of those reacting to the test. The value of testing the first-year pupils is helpful in finding the source of infection since the positives were most likely infected in the home. Testing the seniors serves to uncover clinical tuberculosis in the individual or prove freedom of tuberculosis upon graduating. With a diligent search being continually made to find the cure of tuberculosis as early as possible and see that the proper treatment is instituted at once both to give the patient the best chance to recover and protect the public much will have been accomplished. The county making such a whole-out effort will see the death rate falling and may soon be in a position to become accredited.

The State Medical Association and the State Board of Health decide when a county has met the necessary requirements for accreditation. The certificate is given by the two organizations. In addition to the proper endorsement by both of these organizations the certificate bears the Seal of the State and signature of the Governor, and is presented to the county board of the county meeting the necessary requirements. This is an event any county can take pride in and every county can strive to achieve. It will stimulate greater interest in the fight against tuberculosis than anything previously undertaken in the state.

The death rate from tuberculosis has risen following every great war. It is the hope that the increased effort stimulated in this state will spread to others and thus prevent history from repeating itself, and that we shall see the death rate continue to fall. Other states are watching Minnesota in this undertaking. It is the hope of the State Medical Association that every physician will help make it a success, thus establishing Minnesota as a leader in a new undertaking for the control and eradication of tuberculosis.

PANIC IS FEARED

Panic is feared even more than poison gas by those charged with the defense of the civil population against possible chemical attacks, Prof. Chauncey D. Leake of the University of Texas stated. People do not know about war gases, and they are afraid of them; but "Tell the people the truth about war gases and they will probably respect them more and fear them less," he said.

Some fumes that arise in certain types of fires may be mistaken for poison gases spread by the enemy, Prof. Leake pointed out, and this can give rise to reports of chemical attacks that have not actually taken place.—*Science News Letter,* April 24, 1943.

CLINICAL-PATHOLOGICAL CONFERENCE

MINNEAPOLIS GENERAL HOSPITAL

A. J. Hertzog, M.D., and S. V. Lofsness, M.D.
Pathologists

Presentation of a Case
Case A-42-2150

Dr. Hertzog: A forty-nine-year-old white female was admitted to the fracture service of the hospital and expired twenty-six hours after admission as a result of a crushing injury of the chest and fractures of the pelvis and right leg. She had been picked up by the ambulance after apparently having been struck by an automobile. An unexpected finding at autopsy was a marked atrophy of the left cerebral hemisphere. It was our opinion that this gross lesion represented a congenital anomaly. The brain was examined by Dr. A. B. Baker and Dr. Harold Noran of the Department of Neurology of the University of Minnesota. Dr. Baker and Dr. Noran were kind enough to come over today and present their findings.

Dr. Noran: I have been able to obtain some additional history. As the only informant was a younger sister, the history of the patient's early years is not entirely complete. The sister stated that the patient, at 10 days of age, became extremely ill and developed a right-sided hemiplegia. The condition was regarded as brain fever. Even though the hemiplegia persisted, she gradually became able to walk for long distances but only partially regained the use of her upper extremity which was always held in a fixed position. She forced herself to use her afflicted arm a great deal without any apparent improvement in its strength. She started school at the age of eight years. However, after reaching the second grade, her parents were informed that she was subnormal and not capable of continuing in school. She was tutored at home for several years, but this was later discontinued because of her slow progress. She learned to read and write, but her ability along these lines was less than that of a seven-year-old child. Her chief activity consisted in helping with some of the less complicated household duties. She was never able to handle any form of responsibility. Throughout her life she remained at a childish level, continuing to play with dolls. She also revealed emotional instability manifested by temper tantrums. Early in life she developed epileptiform seizures which occurred at about monthly intervals. The seizures were characterized by spasm of the entire body, loss of consciousness, and foaming at the mouth. They were often prolonged and inhalations of chloroform were often required to stop the seizures. The convulsions ceased abruptly at the age of twenty-five years. Between the ages of thirty and forty, three apoplectiform seizures appeared. These consisted of a sudden loss of consciousness which lasted for about twenty-four hours and were followed by generalized weakness of about one week's duration. There were no neurological residuals following any of these attacks. At about this time the left eye required enucleation because of a severe inflammatory lesion. During the last few years of her life, she gradually lost her memory so that she failed to recall where she had placed certain familiar articles. Nevertheless, her memory as regards certain dates and events was not impaired. More than one question at a time would often confuse her. During all this time there was no notable change in her hemiplegia. As Dr. Hertzog said, the immediate cause of her death was an accidental injury, and we are only reporting the finding in the nervous system.

External examination of the brain, as shown by this lantern slide, shows that the left cerebral hemisphere is much smaller than the right. The frontal lobe is markedly atrophic and has lost most of its normal architecture. A lateral view of the brain shows, in addition, an almost complete absence of the temporal lobe which has been converted into a thin membrane. The adjacent portions of the parietal and occipital lobes are also somewhat atrophic. Sections through the brain show a marked destruction of the left frontal lobe by numerous large and small cystic areas. The thin band of tissue remaining in these areas is firm and fibrous. There is marked dilatation of the anterior horn of the lateral ventricle which appears secondary to the tissue destruction. The temporal lobe is represented merely by a thin membrane of tissue.

Microscopic sections of both frontal and temporal lobes are similar, as they show almost complete destruction of the cortex. The inner layers of the cortex are replaced by this cystic degenerative process. There is a complete devastation of nerve cells associated with a considerable glial proliferation. We can see on this slide numerous small globules of calcification resulting from a deposition of calcium salts within small hyaline blood vessels. Throughout the white matter there are extensive diffuse areas of demyelinization, as well as focal areas of demyelinization, with beginning cavitation. Glial nodules are also seen scattered throughout areas of the brain that appear grossly normal. Scattered throughout both cerebral hemispheres are perivascular accumulations of lymphocytes. These perivascular infiltrations are also seen in the basal ganglia and brain stem. In addition, a few scattered foci of polymorphonuclear neutrophiles are observed. A marked proliferation of the lining endothelium of many of the small blood vessels is also found.

Discussion

Dr. Noran: The lesions in this case are so similar to those of a proven case of the western variety of chronic equine encephalitis, that we feel we are justified in concluding that it is also a case of chronic equine encephalitis, even in the absence of neutralizing virus studies. We believe the primary lesion is a widespread involvement of the blood vessels that leads to extensive areas of demyelinization and cystic degeneration. As the history in this case goes back to infancy, it shows that the virus may remain active for long periods.

Dr. Lofsness: Do you mean that these anatomical lesions would allow you to differentiate equine encephalomyelitis from the St. Louis variety?

Dr. Noran: In our opinion the lesions in both the acute and chronic cases of equine encephalitis are sufficiently characteristic to allow one to make a specific diagnosis. The striking features in this case are the extensive demyelinization, cavitation, and vascular calcification. These findings do not occur in other types of encephalitis. In the acute cases of equine encephalitis that we have studied, we found many vessels that showed marked proliferation of the vascular endothelium and some of the larger vessels were occluded by suppurative and nonsuppurative thrombi. We feel that if these patients had survived the acute phase of their illness, extensive areas of tissue destruction would no doubt have followed. Some youngsters, after recovery from equine encephalitis, show epileptiform seizures. Encephalographic studies in some of these cases with convulsions have shown a gradual enlargement of the ventricles. There have been cases reported, such as this case, under the title of congenital aplasia of the brain. However, there is no proof that the process was present at birth, and I have the conviction that these cases represent unrecognized cases of equine encephalitis.

Student: Do you think that the pathological processes are going on in these brains for years?

Dr. Baker: I think that what happens is that the equine virus does not disappear from the cells of the nervous system after the patient recovers from the actue stage. If the virus had disappeared from the body, then the patient would recover completely. In spite of the fact that the acute stage is over, the virus caused endothelial proliferation, and by producing calcification within the vessels leads to gradual atrophy and infarction of the brain tissue. Hence, I have the feeling that the virus of equine encephalitis may remain active for many years after a patient apparently recovers from the disease from a clinical standpoint.

Student: Do electro-encephalograms help you in a study of this disease?

Dr. Noran: You would no doubt obtain changes in the electro-encephalogram, but I do not believe they would be of any help from a diagnostic standpoint.

Dr. Arthur: Were the changes in the brain in this case localized?

Dr. Noran: They were most marked in the frontal and temporal lobes, but there was a diffuse involvement of the entire brain.

Dr. Baker: The largest epidemic of equine encephalitis in the United States was in this district. There were approximately 700 cases. We will probably continue to have equine encephalitis in Minnesota and the Northwest until we learn how the disease is spread. We will have to be a little cautious in the prognosis, as even after clinical recovery we cannot guarantee that there will not be a recurrence of the disease. In those patients that recover, they may still show small areas of focal damage. This is not enough to produce symptoms, but if the patient lives long enough they may cause trouble.

Interne: Do you think that equine encephalitis is a new disease?

Dr. Baker: I think that we saw cases of it, but it was not recognized. It has, however, shown an increase in both horses and men.

Dr. Hertzog: The immediate cause of death in this case was a crushing injury to the chest and fractures of the pelvis and right leg. In view of the history of hemiplegia beginning at the age of ten days, ones first impression would be that the cerebral findings were on a congenital basis. Dr. Noran and Dr. Baker have shown us why they consider this case to be chronic equine encephalitis. I want to thank them for coming over today.

WASTE FAT SAVING

Physicians are urged by the Waste Fat Saving Committee, with headquarters in New York City, to set an example in the saving of fat in their households. Waste household fat should be saved and returned to the meat stores which are prepared to pay the prevailing price for kitchen fats or to accept them as gifts to the war effort. This saved fat is turned in to the renderers to make up the 200,000,000 pounds desired for 1943.

The glycerine derived from fats is desperately needed to feed the United Nations' war machine. It is the source of nitroglycerine and dynamite, is used in paint, as an anti-icing fluid for the propellers of airplanes, on shock-absorbers of jeeps, the recoil mechanisms of big guns and the firing mechanisms of depth bombs.

Glycerine is also widely used in medicine. More than three pounds of glycerine per hospital bed are used in our hospitals. With the sole exception of water it is the most used liquid in medicines.

It is said that every pound of waste cooking fats will provide enough glycerine to make a half pound of dynamite or four 37-mm anti-aircraft shells.

Fat saving, though bothersome, is one of the important activities which will play a part in the successful prosecution of the war.

HISTORY OF MEDICINE IN DODGE COUNTY

BY JAMES ECKMAN
Rochester, Minnesota

and

CHARLES E. BIGELOW, M.D.
Dodge Center, Minnesota

(Continued from April issue)

The year 1869 in Dodge County medicine was enlivened by professional bickering so fierce that the editor of the *Dodge County Republican* of Kasson thought it necessary to admonish certain physicians in his newspaper. It seemed that a physician in Mantorville had prepared a paper on the cause and treatment of pulmonary tuberculosis. This paper had been published in the *Mantorville Express.* Another Mantorville physician, in a succeeding issue of the *Mantorville Express,* had attacked the first physician "with the ferocity of an angry bull-dog, which seems to us," declared the *Dodge County Republican,*[33] "is neither professional, courteous, or gentlemanly deductions. . . . Such wrangling is unworthy the profession; and we advise the learned doctors to act the part of gentlemen at least. It is bad enough for the community to swallow their nostrums, without being compelled to swallow such a sickening dose of spleen and 'bad blood,' and the *Express* is made the funnel through which this sickening dose is administered to the public."

Probably there were other professional feuds and encounters, also; but as a rule such difficulties are not perpetuated in print. It may be said, parenthetically, that both men involved in the aforementioned disagreement were entirely competent physicans of excellent standing.

The Minnesota State Medical Society was reorganized in 1869, and someone in Dodge County reported to the society at its first semi-annual meeting at Owatonna on June 16, 1869, that there were four regular practitioners of medicine and two irregular physicians in the county that year.[42]

The first physician in Dodge County to become a member of this society was elected to membership at the aforementioned session at Owatonna. He was **Dr. O. W. Sadler** of Concord, and he seems to have ranged about Southern Minnesota rather widely in the sixties and seventies. He had come from the East (presumably from Pennsylvania, like Doctor Potter), and is known to have been in active practice in Concord in 1870. On the other hand, in a directory of the city of Wabasha contained in a history[43] of Wabasha County printed in 1870, Doctor Sadler was listed as having an office on Washington Street in Wabasha. Perhaps he maintained an office in Concord and another one in Wabasha. Again, he may have practiced in Winona.*

*In various sections of Minnesota the practice of a physician's maintaining an office in several villages is still existent. In some cases in which a single village cannot support a full-time resident physician, this procedure affords the only means of providing medical care for the villagers concerned. Itinerant quacks as a rule, particularly in the early days, did not maintain offices in the towns which they visited periodically; rather, they used hotel facilities and carried their equipment with them.

It was reported[44] that in 1870 Doctor Sadler had taken part in a consultation with Doctor Garver and Doctor Willson in a case involving insanity, and it is known that in 1871 he tendered a bill for $54.00 to the commissioners of Dodge County for medical services rendered to the destitute of the county.[45] It would be desirable to learn more about this frontier physician who was the first in his county to affiliate himself with the newly reorganized state medical society, but efforts of the authors thus far have not been particularly successful in such a quest. A few data have come to hand. For instance, Doctor Sadler's name is printed in the list of members of the Minnesota State Medical Society in the society's *Transactions* for a number of years, and in each list he was indicated as residing in Concord. His name is to be found in the list of members in the *Transactions* of 1875, but not in the *Transactions* of 1876. It is probable that by the last-named year he had already left the state. It is believed that he went to Pittsburgh. He styled himself an "eminent oculist"[46] and in July of 1875 made it known[47] that he was operating for "crossed eyes" at the Bradley House in Mantorville, while he was back in Minnesota for a visit. He visited Mantorville again in 1879 with his wife, and then "returned to Philadelphia [*sic*]."[48] In the summer of 1890 it was recorded[49] that Mrs. Sadler and her child, "from Pittsburgh, Pa.," were visiting in Mantorville. She was the former Emma Josephine Slocum of Mantorville, whom Doctor Sadler had married at some time in the late sixties or early seventies.[50]

The Return of Adversity, 1870-1880

It is possible to reproduce something approximating the vital statistics of Dodge County for the year 1870, since a history[5] of the county issued in that year contained what were said to be excerpts from the census, probably not official. There were 8,686 people in the county, of whom 4,592 were males. Of these, only 1,900 were American citizens eligible to vote.* There were 4,094 females, which would indicate, numerically at least, that females desirous of acquiring husbands should not have been at too great a disadvantage, since as stated there were 4,592 males. There were 1,599 families, members of which occupied 1,557 dwelling houses.

Deaths were distributed according to the following causes:

Pulmonary tuberculosis	8	Dropsy	2
Drowning	3	Childbirth	1
Measles	4	Epilepsy	1
Typhoid fever	2	Inflammation	1
Congestion of brain	2	Diphtheria	1
Old age	2	Disease of kidneys	1
Puerperal fever	1	Softening of brain	1
Chronic diarrhea	1	Whooping cough	3
Cancer	1	Gangrene of wound	1
Killed by lightning	4	Unknown	9

The seventies in Minnesota, and particularly in the southern rural counties, are remembered for the years of the locusts and the panic of 1873. In June of 1873 a tremendous torrent of locusts inundated the Western Minnesota farmlands, coming from Dakota and afflicting at least thirteen southwestern counties in Minnesota.[51] So voracious were they that the yield of wheat on lands which they visited was reduced to less than six bushels an acre.[51] Entire families of

*Readers doubtless will recall that the nineteenth amendment to the Constitution—"The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of sex"—did not become effective until August 26, 1920.

settlers were left penniless, many of them with the added catastrophe of an unsatisfied mortgage.* The locusts returned in 1874, 1875, 1876 and 1877. Nevertheless, bumper crops were produced in Dodge County in 1877, to judge by contemporaneous newspaper reports.

It is not generally realized that the locusts ranged as far to the east as Dodge County, but newspapers of the county mentioned the pests frequently, particularly in 1873 and 1874. In 1877 a dual menace afflicted Dodge County—"chinch-bugs and tramps"—and in 1878 the affliction, although somewhat different from that of 1877, was again double—"hard times and diphtheria."

Railroad building had come to a standstill in the fall of 1872, and during the next year the panic of 1873 descended upon the people. Prices for agricultural products of all kinds declined fearfully, but in general the cost of transporting these products from the farmlands to the metropolitan markets remained comparatively high. Moreover, a cycle of national deflation was in motion, and it was not to be completed for several years to come.

Yet, panic, locusts or lack of inland transportation did not deter physicians from locating in Dodge County from 1870 to 1880.

In June of 1870 it was announced[52] that **Doctor Stephen W. Ranson** (1843-1904) had hung out his sign in Dodge Center. Doctor Ranson was to remain in this town until his death. He had been born in Michigan, as will be shown, but had been reared in Dodge County, and had returned to the county to practice medicine after his graduation from the Chicago Medical College in 1870.

Another physician who settled in Dodge County in 1870 was **Doctor James Manning Saunders** (1816-1904). He came from Milton, Wisconsin, to locate in Dodge Center in October of 1870, although at that time he did not have the degree of Doctor of Medicine. Like Doctor Ranson, Doctor Saunders remained in Dodge Center for the rest of his life. He was graduated from the Hahnemann Medical College and Hospital of Chicago in 1871, and was one of the founders of the Southern Minnesota Homeopathic Medical Society at Owatonna in October of 1871, as has been shown elsewhere.[53]

In the summer of 1871 the *Dodge County Republican*[54] of Kasson observed that Minnesota air, "as usual" was very clear, that there was very little illness, and that "our M.D.s have little to do."

Two physicians are known to have settled in Dodge County in 1873. **Doctor Christopher Porter Gibson** (1848-1933), who had been brought to the county in 1856 with his parents, was graduated from the Chicago Medical College in the spring of 1873 and returned at once to Dodge County, where he located in Dodge Center. He remained at Dodge Center until 1881, when he moved first to Fairpoint in Goodhue County and then to Concord in Dodge County. He went to Redwood Falls in 1889 and practiced there until 1912.

"Dr. Horace Porter called at our sanctum this morning," the editor[55] of the *Dodge County Republican* of Kasson observed in December of 1873. "We learn that he is considering locating somewhere on this line of railway. His large civil and military experience will recommend him to any community."

This was **Doctor Horace P. Porter** (1838-1912), a graduate of the Medical Institution of Yale College who had come to Dodge County from Western Michigan. He decided to locate in Kasson, but remained there for slightly less than a year, going to Claremont in September of 1874.[56] At Claremont in December

*For an especially vivid account of the ravages of the locusts in one Southern Minnesota county, and of methods adopted to combat them, see: Moro, A. R.: The English Colony at Fairmont. Minnesota History, 8:140-149, (June) 1927.

of 1874* Dr. Porter began to issue a curiously flamboyant four-page newspaper called *The Wind Mill,* "issued when we feel like it" and "circulation immense." It was printed at Kasson and distributed at his own expense. The salutatory editorial in this odd publication follows:

In accordance with a time honored custom, the embryonic, or, to speak more "korrectly," the new born publisher is expected to apologise for—for—for what? Well, for being born "anyhow." But we can't do it. It is of no use. The tremendous rush of advertising not only abridges our space for editorial strategy, but absolutely crowds out our home and foreign correspondence. A host of choice and racy sketches from all the larger cities of Europe and America will be utterly lost to the anxious readers of this issue of our paper. We wanted to say something. We are pregnant with ideas, and the strain on our editorial safety valve is immense. Several cash advertisers are waiting for space in our second number, and we shall have to endure the suspense. None but those similarly situated can appreciate our heart-rendering situation. It is obvious to every one that this is a four-page paper. We have never measured its periphery, consequently we can't give its dimensions. But that is not necessary. "Shaver" will do that. Shaver is a man of inches. He has had his editorial measuring rod into about every newspaper in the country. He will deliniate with mathematical exactness our precise length and breadth, including area and solid contents. But we are not in a fault-finding mood. Shaver is a good fellow, with

Just enough of naughtiness
To give him an appearance
Of editorial jauntiness.

He is as fine a craft—sitting low, rakish and handsome on the editorial waters—as ever spread its literary sheets to the breeze of public opinion. We have had him after us before, and can speak authoritatively of his soiling qualities.[57]

The "Shaver" referred to in this editorial was Ulysses Bishop Shaver (1827-1898), an Ohioan who founded the *Dodge County Republican* at Kasson in 1867.[58] What Doctor Porter meant by "We had had him after us before" can only be surmised.

In the same issue of this little four-page unpaginated sheet Doctor Porter observed that "The plague is on the decline. No new case to report, and the sick are all mending.[57]

Numerous references to the status of the public health in Claremont were printed in *The Wind Mill.* In the issue for December of 1875 Doctor Porter observed that:

We still have an abiding faith in the future prosperity of this little hamlet. The chronic sores so wittingly referred to by the genial editor of *The Kasson Republican* are all healed, and the scars are fast disappearing. A healthy nutrition pervades the entire system of our village economy, and we are destined to come a "town." . . . Please stand up for Claremont, gentlemen, and lean heavily upon anybody who persists in the exhibition of a dog-in-the-manger spirit.[59]

In the issue[60] for May of 1876 he said:

We need a public well located in some accessible place on the high ground south of Front Street. There are but few wells of really wholesome water in town.

Later in the year he said that:

The Western part of Dodge County is, at the present time, in the full enjoyment of almost universal immunity from disease. If the grasshopper stays away ten years, real estate will quadruple in value, perhaps in less time. A few years of patient industry and careful economy will make this country the garden of the Northwest.[61]

In the same issue he declared that "A stove-pipe hat, a gold watch and a profound look of 'almightyism' don't make a man a Doctor in this country or any other."[61] It would be hard to determine against whom this shaft was directed, for it may have been intended for some transient quack who happened

*"Dr. Potter is very busy," the *Dodge County Republican* observed in a Concord news note in the issue of December 21, 1874. It is thought that this was Dr. J. M. Potter, an eclectic physician, but this is not certain. He may have been in Concord from 1871 to 1875. Mrs. Mary Wheeler of Concord recalled that Dr. Potter of Concord attended her sister when the latter died in Concord on December 21, 1874.

to be in Claremont at the time, or for some physician not resident in Claremont.

"Just now we are being deluged with veterinary surgeons," Doctor Porter reported in this issue[61] (December, 1876), "All of them experienced men, and by the way the field is ample. We never saw so many cropped horses before."

He also presented a short description[61] of Claremont as he saw it in December of 1876:

> We told you two years ago that Claremont was destined to prosper. Since the first number of this paper was issued the population of the village has about doubled. Real property has appreciated about 100 per cent., and still they come, and new buildings continue to go up. We now have two stores carrying general stock, one hardware and one drug store, a good hotel, three blacksmiths, a harness maker, wagon maker, and a first-class shoe-maker; a millinery establishment, two first-class lumber yards, a furniture establishment on the way, the best wind-power flouring mill in the State, a doctor [Porter] of 16 years military and civil experience, a real estate and insurance office, the best elevator of the line of the Winona & St. Peter R. R., two grain buyers, a good school presided over by the tallest and best school teacher in the State, religious services by an eminent divine at regular intervals; and all things considered we ought to be satisfied with the progress we have made. And we would say to our farmer friends in view of the short crops and hard times, don't you think you had better stay by your own commercial center, your town, and spend your money in a sphere wherein a portion of it at least will not be wholly beyond your reach?

Reference to a physician outside Dodge County who was already well known in Southern Minnesota was made by the *Dodge County Republican*[62] of Kasson in 1873. This newspaper reprinted a short news item from the *Rochester Record* in which it was said that **Dr. William W. Mayo** (1819-1911) was planning to move to Saint Paul in association with **Dr. Charles Hill** (1826-1914) of Pine Island. "He has been here for ten years," the *Rochester Record* observed of Doctor Mayo. A picture of Doctor Hill owned by the Minnesota State Medical Association shows him to be a lean, angular man with a formal, square-cut coat which reached to his knees and a tall hat such as was worn generally in the forties and fifties. He was an old friend* of Doctor Mayo, but the two men never made the removal to Saint Paul mentioned in the *Rochester Record.*

The year 1874 was marked by the death of **Dr. Josiah R. Dartt** of Mantorville. The funeral ceremonies were witnessed by one of the largest crowds ever to assemble in Dodge County.

In 1874 a work called *An Illustrated Historical Atlas of the State of Minnesota* was published by A. T. Andras of Chicago, and was printed by a house which has since become world famous for fine printing and publishing—R. R. Donnelley and Sons Company, operating the Lakeside Press of Chicago.[63] This ornate atlas was issued under the sponsorship of a list of "patrons." Among the "patrons" in Dodge County were Doctor Bedient, Doctor Garver, Doctor Ranson, Doctor Saunders and Doctor Porter.[64]

Dr. Nils Schultz Holterman (1845-1895) came from Saint Louis, Missouri, at some time in 1874 to settle in Kasson. He was a Norwegian physician who had intended to settle in Chicago, and had reached that city from Norway just before the great holocaust of 1871. He remained in Kasson until 1878.

"Thirty years later, when Doctor Hill was seventy-seven years old, he was elected first vice president of the Minnesota State Medical Association. Asked for a speech, he replied (in part): "Near me is a great hospital that was scarcely known fifteen years ago, that has now a national and, I might say, an international reputation, and it is presided over and is the work of young men. The Mayos are geniuses. I live within fifteen miles of Rochester and a good many people go there that might otherwise come to me, but I have no feeling in the matter. I have nothing against such men; I am proud to know them, and I am glad to live near them."—Transactions of the Minnesota State Medical Association, Thirty-Fifth Annual Meeting, held at Saint Paul, Minnesota, June 17, 1903, Chicago, Press of American Medical Association, 1904, pp. 24-25.

In May of 1874 **Dr. John J. Everhard** moved from Mantorville to Kasson.[65]

Dr. H. B. Young came to Kasson in July of 1875, to remain there for about a year. In May of 1876 he departed with his wife for New York, there to sail to Europe for further study in medicine. It is believed that Doctor Young settled in the East when he returned from Europe, but nothing more is known about him.*

In October of 1875 **Dr. Henry T. Turner** (1837-1913), an eclectic physician, settled in Kasson, where he stayed until about 1889, save for a short interval which he spent in Minneapolis. Eventually he served as health officer of Kasson.

In December of 1875 Doctor Garver moved from Wasioja to Dodge Center, and about a month later he announced a partnership in Dodge Center with Dr. Christopher Porter Gibson[66] (1848-1933).

Dr. Curran W. Higgins (1849-1926), who had been reared in Dodge County, schooled in homeopathic medicine by **Dr. William Huntington Leonard** (1825-1907) of Minneapolis, and graduated from the Hahnemann Medical College and Hospital of Chicago in 1876, came to Concord for a very short while in 1876. Woods[13] said that Doctor Higgins never practiced medicine in Concord, but Moreland[67] said he did. Doctor Higgins soon went to Corning, Iowa, and from that town to Brookings, Territory of Dakota. His career will be recounted later.

In 1877 newspapers reported a new fad in Dodge County: the use of blue glass in windows of many homes in the county.† The belief was that the sun's rays, filtered through such glass, would cure chronic conditions if persons so affected would sit in the transmuted rays for indefinite periods. Some of these windows are still to be seen in some of the older houses.

Oliver H. Phillips (1834-1905), editor of the *Dodge Center Press,* remarked in his newspaper on April 19, 1877, that "Doctor Steere did some work on our masticating apparatus . . ." In the same issue the professional card of this man appeared:

W. B. STEERE, M.D.
Resident Dentist
Teeth extracted without pain.
Prices low and work warranted.
DODGE CENTER, MINN.

Doctor Steere was not a dentist by training. He had been graduated from the old Eclectic Medical College of Philadelphia on January 22, 1862, and probably had come to Minnesota from DeWitt, Iowa. He remained in Dodge Center until 1881, in which year he removed to Pierre, Territory of Dakota, as will be shown. He was never licensed to practice medicine in Minnesota.[40]

*But a Dr. Arthur B. Young located in Winona in July of 1876. In March of 1884 he was living in Prescott, Wisconsin. The authors do not know whether or not he was the same Doctor Young mentioned above. See reference 213.

†This fad was not confined to Dodge County, by any means. For instance, in 1871 General Augustus J. Pleasanton issued his *On the Influence of the Blue Color of the Sky in Developing Animal and Vegetable Life* (Philadelphia, 1871), and in 1877 appeared his *Influence of the Blue Ray of the Sunlight and of the Blue Colour of the Sky, in Developing Animal and Vegetable Life, in Arresting Disease, etc.* (Philadelphia, 1877), printed throughout on blue paper.

(To be continued in the June issue)

President's Letter

"The failure to coördinate knowledge and action is all too common in our efforts to control and eradicate tuberculosis."

(Quotation from *Tuberculosis Abstracts* by the National Tuberculosis Association)

THERE is an inherent inertia in the make-up of human beings, a tendency toward laissez faire, sometimes called conservatism, which impedes the acceptance of any new idea, and delays the utilization of any new knowledge. It is doubtless true that "knowledge is power," but power is only an attribute or property of the possessor of it which merely makes it possible for him to do or effect something. In every field of human endeavor we find failure to coördinate knowledge and action, or, more accurately, to translate knowledge into action. "There is nothing new under the sun" and old knowledge which has long lain dormant and useless for want of action, is continually being dug up.

The years 1882 and 1895, in which, respectively, the germ of tuberculosis and the x-ray were discovered, mark the beginnings of the acquisition of the knowledge on which the control of tuberculosis is based. Thirty years later, the control of this disease, even in cattle, still seemed to many veterinarians to present obstacles which were impossible to overcome. The program of testing of herds of cattle progressed but slowly and in spite of much opposition, Minneapolis has the distinction of being the first city in the United States to require that no dairy products be sold within its limits unless they came from cattle which had been tested with tuberculin. The idea of "area testing," or testing of all herds in a county was first tried in the early 1920's. The State of Minnesota was one of the leaders in adopting the program of "area testing" and by December 1, 1925 four counties in Minnesota had become "Accredited Areas." By 1935 every county was accredited.

The success of the area testing program in the control of bovine tuberculosis inspired the Committee on Tuberculosis of our Association to work out plans for a similar program with respect to human tuberculosis, and Minnesota has the distinction of leading the nation in the application of this plan.

Two of the four counties above mentioned are entitled to especial distinction. Murray County was the fourth county in the State to be Accredited for Bovine Tuberculosis Control in 1925, and was the third county in the State to qualify for Accreditation for Human Tuberculosis Control. Meeker County was the third county of the State to be accredited for Bovine Tuberculosis Control in 1925. Besides this, it has inaugurated a unique plan for the control of human tuberculosis. The Meeker County Plan has attracted nation-wide interest and has received financial support from the American Medical Association from the Minnesota State Medical Association and from philanthropic individuals.

Our Association may feel justifiable pride in the work of its Committee and members in thus placing Minnesota among the leading states in the Union in the control of tuberculosis. The accusation of failure to coördinate knowledge and action cannot be sustained against Minnesota.

STATE MEETING

THE ninetieth annual meeting of the Minnesota State Medical Association will be held May 17, 18 and 19 at Minneapolis. The complete program appears in this issue.

With national medical meetings suspended for the duration, emphasis has been placed on the importance of local and sectional meetings which require less travel. Meetings of state associations fall into this category.

The program includes some subjects relating to war medicine. As a whole it should prove of value to the general practitioner. One of the two sections will be taken up largely by scientific cinema. Of practical value will be the Round Table discussions scheduled for the luncheon periods Tuesday and Wednesday.

Owing to illness, Dr. Ralph S. Bromer of Bryn Mawr, will be unable to deliver the Russell D. Carman Memorial Lecture. The lecture will be delivered by Dr. Edward L. Jenkinson, Associate Professor of Radiology, at Northwestern University Medical School. The other guest speakers will be Dr. Frank C. Neff, Professor of Pediatrics at the University of Kansas School of Medicine and Captain E. G. Hakansson of the United States Navy who will speak on "Tropical Diseases."

One of the outstanding features of the meeting will be the address by the Honorable Walter H. Judd, congressman at Washington from the Fifth District, who will speak at the banquet Tuesday evening on his experiences in Washington.

Various phases of the child problem during wartime will occupy Wednesday afternoon. Public health nurses, social welfare workers, members of parent-teacher associations and all others especially interested in child health are invited to attend.

The business side of the meeting will be largely completed on Sunday preceding the convention. This will enable delegates and officers to take advantage of the scientific program.

Members, although busier than usual this year, would do well to make every effort to take advantage of the stimulus which will doubtless again be afforded by our State Meeting.

PROPAMIDINE

ATTENTION was called in a recent editorial[1] in the *Journal of the American Medical Association* to a new drug which apparently represents a distinct advance in preventing, but more particularly in removing, infection from streptococci and Staphylococcus aureus in burns and wounds.

Four reports[2,3,4,5] of experience with propamidine (4:4 diamidinodiphenoxy propane dihydrochloride) recently appeared in *Lancet* which are convincing as to the value of this new drug.

The local action of sulfonamides seems to be inhibited by the peptones and other constituents of pus and tissue fluids; not so with propamidine. Used in a 0.1 per cent strength in a watery gel of 5 per cent methyl cellulose, Thrower and Valentine,[5] found that acute and chronic infected wounds were freed from streptococci and in most instances staphylococcic infection in two to ten days. Wounds are cleansed with sterile saline solution and the gel is applied directly with vaseline strips placed over the wound. The dressing is renewed in forty-eight hours and the treatment is limited to ten days. There is some danger of skin irritation from action of the vehicle rather than the propamidine if it contacts the skin, and prolonged use beyond the ten-day period is not recommended.

Some of the authors mentioned used propamidine in 0.1 per cent strength in a Mumford base (lanette wax and paraffin) and found that the addition of 1 per cent stovaine rendered this preparation particularly suitable in the treatment of painful burns. The use of the preparation in recent burns prevents infection and hastens repair.

Propamidine will doubtless become available

and wider experience should substantiate the experience so far reported.

SPANISH AND PORTUGUESE IN MEDICAL SCHOOLS

WORLD War II has without doubt led to a fuller realization in our own country, but to a greater extent in the countries of South America, of the fact that North and South America have certain common interests. It is to be hoped that following the war this more friendly feeling will increase and that the suspicion with which we were regarded in certain South American countries and which was fostered by certain European propaganda will disappear. The two continents are natural rivals in world markets for agricultural products, but this should not prevent a friendly feeling and coöperation between the countries concerned.

Doubtless one reason for lack of understanding between the peoples of South America and those of Canada and the United States is that they do not speak the same language. Spanish is the language of all the South American countries except Brazil. This means that half the people of South America speak Spanish and the other half Portuguese. English is taught in the schools much as German and French are taught here, which means that most of those who have studied English do not read or speak it readily. The presence of more Englishmen in Argentina doubtless accounts for English being taught more in that country. The American movie has been more of a stimulus to the understanding of English than any other factor. Most of the talkies are in English with Spanish or Portuguese captions interspersed. These are more popular than the few which are produced in Spanish or Portuguese for South American consumption.

Science, particularly the science of medicine, should have no international boundaries. One and two generations ago a knowledge of German was considered essential for the well-trained American physician. With the rapid progress of scientific medicine in America the knowledge of German has not been so essential. Hitler's regime has temporarily interfered with Germany's medical progress, although we should not forget that the value of sulfa compounds was discovered in the late thirties in Germany. It is not beyond the realm of possibility that German medicine will regain a position of importance following the war.

German medical literature has had the leading position in medicine in South America. This source of supply is now completely shut off. American medicine has been of less importance in South America than perhaps it should. Regulations have made it well nigh impossible for an American physician to practice in South America. This state of affairs, however, has not existed as far as the American dentist is concerned. There, as well as in Europe and the rest of the world, the American-trained dentist has had a well-deserved outstanding position.

Efforts have been made to increase and improve our relations with the medical profession of South American countries. American medical organizations have visited their professional brethren in South American countries and have been impressed with the character of the medical work in various quarters. Pan American congresses have been conducted to further understanding and exchange of ideas. In an effort to supply American medical literature sources to South American physicians *America Clinica,* containing abstracts of current medical literature, is printed in Spanish and aims at an extensive distribution.

In an effort to overcome the language difficulty, which interferes with mutual understanding and interchange of scientific knowledge, the American Urological Association at its meeting last June drew up a resolution to the effect that the teaching of Spanish or Portuguese in our medical schools should be required. The resolution further recommends the encouragement of the training of South American students in the medical schools of Canada and the United States. Making the study of Spanish or Portugese mandatory in the already full curriculum of our medical schools seems extreme. Nevertheless, the idea of the desirability of a knowledge of these two languages on the part of our profession should be endorsed.

THE HEART PROGRAM OF THE BUREAU FOR CRIPPLED CHILDREN

The Social Security Act passed in 1935 authorized the appropriation of Federal funds for services for crippled children. These funds are paid to the states after annual State plans for such services have been approved by the Chief of the Children's Bureau of the United States Department of Labor.

The child with rheumatic fever or heart disease may be included in the definition of a crippled child.

Minnesota's plan for the care of these children was approved by the Minnesota State Medical Association in December, 1941, and approved by the Children's Bureau in February, 1942. It is administered by the Bureau for Crippled Children of the Medical Unit of the Division of Social Welfare. Children under the age of twenty-one with heart disease or conditions leading to heart disease are eligible for care.

The child must reside in the limited area which is served, but legal residence is not required. This area includes Scott, Dakota, Carver, McLeod, rural Ramsey, and rural Hennepin Counties. Minneapolis and Saint Paul residents are not accepted. The area had to be limited because of lack of funds, and because the Children's Bureau has advised the State agencies to start the programs in limited areas, and do intensive work in these areas until funds are available to expand the program.

Emphasis is given to the care of children with rheumatic fever or rheumatic heart disease. However, children with other types of heart disease which offer a reasonable expectation of improvement from treatment are also eligible for care.

Diagnostic services are available to all children living in the designated area. Treatment is given only when the family is unable to provide adequate private care. The approval of the family physician must be obtained before the child is referred to the heart clinic.

A clinic is held each Friday morning at the Children's Hospital, Saint Paul, to provide diagnostic services and follow-up care. Hospital care is provided for the children during acute illness, at Children's Hospital, Saint Paul, under the direct supervision of the heart clinician of the Bureau for Crippled Children. Convalescent care is also given at the Children's Hospital under the same supervision as hospital care.

Foster home care is arranged for children who do not require further hospital care, whose homes are not suitable for continued rest, or are too far from the clinic for close medical supervision. Supervision in the child's own home is important because there may be many adjustments necessary in the home situation to meet any personal and environmental difficulties which obstruct treatment and care of the child. Efforts to meet these difficulties are made either by the personnel of the Bureau for Crippled Children or by other local or State agencies, with joint planning by the heart clinician, the medical social worker, the public health nurse, all of the Bureau for Crippled Children.

From February 16, 1942, to February 15, 1943, there were fifty-two hospital admissions of thirty-six hospital patients, and 133 visits were made to the weekly heart clinics by forty-seven clinic patients. Ten cases were in the hospital on February 15, 1943.

Inquiries regarding the heart program of the Minnesota Bureau for Crippled Children should be directed to Medical Services Unit, attention of Dr. Malvin J. Nydahl, Head, Bureau for Crippled Children, Division of Social Welfare, Globe Building, Saint Paul, Minnesota.

BOOTH MEMORIAL HOSPITAL

The Salvation Army Booth Memorial Hospital was opened forty-five years ago in Saint Paul, Minnesota, and has an unbroken record of service during that period. It provides care for the unmarried mother and her child and works out the solution of those problems peculiar to such cases. This care is provided regardless of creed, class, or color. The Salvation Army operates thirty-seven similar Homes in the United States, where over 7,000 girls are cared for yearly. The Saint Paul Booth Memorial Hospital has given care to 4,975 girls during the years of its existence.

A girl may come to the Home when it becomes necessary for her to leave her present surroundings. It is preferred that she come at least six weeks before confinement and remain until given the six weeks medical discharge. Any further residence in the Home will depend on the formulating of a social plan for herself and baby.

There is a fee of $50.00 for three months' care; fifty cents for each additional day, but never to exceed $80.00. If a girl decides to leave before confinement, there will be a charge of $5.00 a week for the time of her residence in the Home. A girl may not "work out" her fee, though she is expected to assist with household tasks.

A girl from outside the State of Minnesota is admitted only with the understanding that she will return to her own State and community taking her baby with her. She cannot in any way be a charge upon the State of Minnesota.

Infants are not adopted from this Home. They are referred to Placement Agencies; this matter is handled by the Bureau of Child Welfare during the nursing period. This Bureau is notified of a girl's admittance to the Home and collaborates with the Home on all future plans for mother and baby.

Medical services are under the direction of Dr. John L. McKelvey, Chief of Obstetrics and Gynecology at University Hospital. The pediatric service comes under the direction of Dr. Irvine McQuarrie, Pediatric Chief at University Hospital. The Home has complete hospital facilities, registered nurses, social worker, and a staff of trained workers.

Major Venus McAlearney is Superintendent of the hospital, which is located at 1471 Como Avenue West, Saint Paul, Minnesota.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

NEW PATTERN IN MEDICAL SERVICE

In much of the writing about the need for methods of payment for medical services, certain inevitable processes which are likely to have a tremendous effect upon the pattern of medical service are largely overlooked. One of these is the growth of medical service in industry. While discussion has been continuing over traditional battle grounds, it is just possible that a new movement is growing up all around them that will satisfy the demands of both. This movement is an increasing growth of medicine to meet the demands of industry and the war.

Full-time medical service in industry is educating physicians, patients and employers, alike, in the worth and practicability of systematic preventive medicine, prompt treatment, effective rehabilitation and close coöperation among all physicians.

The experience may not be forgotten when war industries shrink and workers go back to their old occupations. The same type of service may be asked for and secured by a great many people whose pre-war contacts with medical service were not as satisfactory or as available.

Employers Are Active

It is interesting to note that employers' and manufacturers' associations are becoming more interested in the economic, as well as the social phases, of systematic health and medical services in their plants. They argue that the industrial development of postwar America will be accompanied by a corresponding development of industrial medicine which will have an enormous effect upon practice outside the plants.

The field in general is new; but sound standards are being developed under guidance of the American Medical Association's Council on Industrial Health. They give promise of preserving medical and ethical standards of practice and at the same time of exploring fully vast new possibilities for improvement of the health and well-being of millions of American workers.

Referred to Family Physician

Except in unusual instances where medical care is not otherwise available, the best standard demands that the sick or injured worker be referred promptly to his own physician for all but emergency treatment. The practitioner outside the plant in theory should see his own employed patients oftener and earlier, and with the advantage of complete information from the plant medical service as to working conditions and hazards. It may be to the advantage of all physicians in the community to coöperate with the plant services and to inform themselves exactly of needs and methods used.

The duties of the physician in the plant medical service, as set out in the Council's outline of procedure, cover a wide range of service. Among these services, preventive medicine assumes an important and interesting role. In fact, there is every reason to believe that the war effort, including both the growing medical services in industry and the extensive examination of inductees, will operate together to establish preventive practice on a hitherto undreamed-of basis after the war.

Preventive Medicine in Industry

Preventive medicine in the industrial plant is divided between supervision and safeguarding of working conditions and the routine examinations of employes. These examinations go far beyond the immediate objective of determining physical fitness for the job. Industrial physicians check at intervals on physical condition and morale, advise the worker on his own habits and prospects, supervise rehabilitation and generally keep him as content and healthy as possible. Complete records are kept; but the record is confidential and the relationship between the employe and the physician is one of mutual confidence and cour-

tesy. Success of the service depends, ultimately, upon the coöperation of the employe; and it is continually emphasized that the industrial physician of today must be far removed from that natural enemy of the worker, the "company doctor," of other days.

Departments Improve

The medical department in large industries was formerly housed in some unused, ill-ventilated and unlighted corner of the shop. Depending upon the size of the plant, the medical department is now a specially designed, completely equipped health center with complete examination, laboratory and x-ray facilities.

Medical and surgical service in the plant is properly limited. It does not extend to families of employes or employers and includes mainly emergency treatment and treatment for minor ailments which temporarily interfere with the worker's comfort.

It is roughly estimated that the time required of a physician for any plant medical service is about one hour a week for each 100 employes. Thus a plant hiring 3,000 workers would require 30 hours a week from its physician or virtually a full-time medical officer together with nurses and technical assistants.

It is also interesting to note, in recent reports of manufacturers association members, that important saving in operational expenses are claimed to the credit of medical departments. One of them in a recent report, credited his department with a definite saving of $6,000 a year over and above the expense involved in keeping up a model plant, fully equipped and manned.

STUMBLING BLOCK

One of the stumbling blocks in the road travelled by all medically sponsored prepayment plans is now discovered to be the subscriber income limit in the contracts.

All plans are geared to the needs of the lower income groups. The trouble is that prospective subscribers do not care to be bracketed for medical purposes in a "low income group."

Shop superintendents and employers (through whom medical insurance must be sold if it is to be a success) are unwilling to foster the sale of contracts and benefits which are not available to themselves and to employes above the income limit.

Labor leaders are likewise opposed to income limits and many employers who might otherwise be well disposed toward such plans fear possibility of labor trouble among their employes.

On the other hand, fee schedules for services to subscribers of nearly all plans have been reduced to the minimum expected of patients in lower income categories and physicians cannot afford to extend their services to employers and higher income groups at the group plan fees.

"Over-Income" Plan

To meet this serious objection, most of the plans now in operation have been forced to provide what they have called an "over-income" service by which benefits provided under the group plan are regarded merely as an indemnity or credit toward full payment of medical fees. The difference between the credit allowed through the group plan and the actual fee to be paid by the subscriber is decided by the individual physician in consultation with the subscriber.

This is the procedure now in effect in California, North Carolina, Massachusetts, Michigan and Western New York. In other states, enabling acts have placed definite limitations on prepayment plans.

Cash payment toward the doctor's fee rather than full payment of his services is the usual plan of non-medical sponsored insurance companies.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

J. F. DU BOIS, M.D., Secretary

Minneapolis Woman Pleads Guilty to Criminal Abortion

Re: State of Minnesota vs. Clara Olga Anderson

On March 25, 1943, Clara Olga Anderson, forty years of age, 925 Chicago Avenue, Minneapolis, entered a plea of guilty in the District Court of Hennepin County, to an indictment charging her with the crime of abortion. The defendant was sentenced by the Honorable William A. Anderson, Judge of the District Court, to a term of not to exceed four years in the Women's Reformatory at Shakopee. The sentence was stayed upon the condition that the defendant serve one year in the Women's Detention Home, commonly known as the Minneapolis Women's Workhouse, after which the defendant is to be on probation for three years.

The defendant was arrested on March 18, 1943, at a St. Paul hotel, following the death on March 15, 1943, of a thirty-seven-year-old Minneapolis married woman. The deceased was admitted to Deaconess Hospital at 2:10 P.M. on March 15, critically ill. The case was promptly reported to the Minnesota State Board of

Medical Examiners and an investigation immediately instituted in coöperation with the Women's Bureau of the Minneapolis Police Department. The case was submitted to the Hennepin County grand jury on March 24, 1943, and an indictment returned charging the defendant with the crime of abortion. Ordinarily, the defendant would have been charged with manslaughter in the first degree, but those in charge of the case were of the opinion that additional medical testimony would have to be available before such a charge could be substantiated. The defendant holds no license to practice any form of healing in the State of Minnesota.

Minneapolis Woman Pleads Guilty in Federal Court to Forging Narcotic Prescriptions

Re: United States of America vs. Helen Geneva Rudd

On April 2, 1943, Helen Geneva Rudd, forty-three years of age, 2305 E. 38th Street, Minneapolis, was ordered by the Honorable Gunnar H. Nordbye, Federal Judge, taken to the United States Hospital at Lexington, Kentucky, for treatment for drug addiction. Mrs. Rudd pleaded guilty on March 2, 1943, to four counts of an indictment charging her with forging medical prescriptions for narcotic drugs. Mrs. Rudd was placed on probation for three years, conditioned, however, that she be taken to the Hospital at Lexington, and that she be not released until the medical authorities of that institution pronounce her cured.

Mrs. Rudd was arrested on January 14, 1943, following an investigation by the Federal Bureau of narcotics and the records indicate that her addiction dates back about twenty years. Mrs. Rudd has a previous conviction for a similar offense, having pleaded guilty in 1934, and after being placed on probation for two years, violated her probation and was taken to the Women's Reformatory at Alderson, West Virginia, where she served fourteen months. She was again arrested in Minneapolis in 1938, for violation of the Minnesota Uniform Narcotic Drug Act, but was acquitted by a jury in October of that year in the District Court of Hennepin County. Mrs. Rudd has attempted in the past to obtain morphine from numerous Minneapolis physicians by complaining of pain and manifesting other symptoms in her attempts to convince the various physicians that she was suffering from gallstones and other ailments.

Minneapolis Woman Found Guilty of Fraudulently Obtaining Morphine Prescriptions

Re: State of Minnesota vs. Alva George

On April 21, 1943, Alva George, forty-three years of age, was found guilty by a jury in the District Court of Hennepin County of obtaining morphine prescriptions by fraud. The defendant was sentenced by the Honorable William A. Anderson, Judge of the District Court, to a term of not to exceed two years in the Women's Reformatory at Shakopee. The defendant was arrested on August 11, 1942, following a lengthy investigation by the Federal Bureau of Narcotics. This investigation disclosed that the defendant was obtaining morphine prescriptions simultaneously from seven Minneapolis physicians. At the trial, and prior to sentence being imposed, counsel for the defendant severely criticized the medical profession, claiming that the defendant was given narcotic prescriptions without any reason. Notwithstanding the fact that the defendant concealed from each of the physicians that she was also getting prescriptions from the others, this case again illustrates the absolute necessity of a complete examination and a careful diagnosis. Morphine should be prescribed only as a last resort and every physician should be on guard, at all times, that the patient may not be telling the truth about the symptoms or the procuring of similar medication elsewhere.

In Memoriam

HENRY PORTER JOHNSON

Dr. Henry P. Johnson, a practitioner at Fairmont, Minnesota, since 1899, died March 31, 1943, of arteriosclerosis and terminal pneumonia following several years of ill health.

Dr. Johnson was born on a farm in Winnebago County, Wisconsin, February 3, 1855. In June of that year his family moved to Winona County, Minnesota. He grew up on a farm, attended rural schools and later the Winona High School and the Winona Normal College. After teaching school a couple of terms he entered Rush Medical College, Chicago, where he graduated in 1879. He began practice immediately and was active until about five years ago.

Dr. Johnson practiced first at Hancock, Minnesota, then at Houston, Minnesota, La Crosse, Wisconsin, and Long Prairie, Minnesota. In 1899 he became associated with his brother, Dr. E. B. Johnson, at Fairmont.

Dr. Johnson married Ruth Ann Warner at Houston, Minnesota, in 1888. Mrs. Johnson died April 15, 1930. Two children survive: Mrs. Nina Johnson Wallace of Saint Paul and Dr. Donald W. Johnson, now in service at Camp Lewis, but previously in practice with his father at Fairmont.

Although one of the first in Fairmont to purchase an automobile, Dr. Johnson also kept a team of horses for use when the roads were not as passable as at present. His teams were known and admired all over Martin County.

While known as a typical family doctor of the old school, Dr. Johnson kept abreast with developments in the medical field and in later years maintained a finely equipped office and hospital in a large modern building which he owned. At the time of his celebration of fifty years in active practice, Dr. Johnson had had nearly 3,000 maternity cases.

Dr. Johnson was a member of the Fairmont school board at one time and served as city health officer. He was a Methodist, belonged to various Masonic bodies and to the Fairmont Kiwanis Club. He was a member of the Blue Earth Valley Medical Society and the Minnesota State and American Medical Associations.

CHARLES F. McCOMB

Dr. Charles F. McComb, former St. Louis county coroner and widely-known Duluth physician, died March 3, 1943, at the age of eighty-five.

Dr. McComb had practiced for sixty years, and was elected coroner eight times. Born in Stillwater, he attended the University of Minnesota and Rush Medical College, graduating from the latter in 1879.

He practiced at Rush City, Minnesota, for two and one-half years after his graduation before taking a

polyclinic course in New York City. Following completion of this course in 1883, he went to Duluth.

He was accorded many professional honors during his long medical career and served a number of organizations as an officer. He was a former president of the Minnesota State Medical Association, was twice president and once vice president of the St. Louis County Medical Society, was first president of the Interurban Academy of Medicine, an organization of Duluth and Superior physicians and surgeons, was a member of the state board of health under three governors, and was a member of the advisory commission of the state sanatorium for consumptives and a member of the American Medical Association.

Dr. McComb also was a member of the state militia and saw active service in World War I as a lieutenant commander aboard the battleship *Iowa*.

He was a member of Palestine lodge No. 79, A. F. & A. M., Aad Temple of the Shrine, Scottish Rite, and St. Paul's Episcopal church.

Surviving are his wife, Helen, and a sister, Mrs. Carrie Maunsell, Minneapolis.

JENS L. OHNSTAD

Dr. Jens L. Ohnstad, for forty years a practitioner at McIntosh, Minnesota, died February 23, 1943, at the age of seventy-four.

Dr. Ohnstad was born at DeForest in Dane County, Wisconsin, June 20, 1868. He attended normal school at St. Ansgar, Iowa, where he graduated in 1892. He taught school in South Dakota and in Fillmore County, Minnesota, before studying medicine at the Minneapolis College of Physicians and Surgeons. After receiving his medical degree in 1903 he studied further at the Polyclinic Postgraduate School in Chicago in 1906 and at the Neiswanger School of Electro Therapeutics in Chicago in 1908.

Dr. Ohnstad practiced in Belgrade for four months in 1903 and in Minneapolis from 1907 until 1909. In 1908 he married Mabel Hooverson of Red Wing. She died in 1918. In 1923 he married Gunda Egeland Jensen at Bemidji. Mrs. Ohnstad and two sons survive.

Since 1910 Dr. Ohnstad had operated his own hospital in McIntosh, the present structure having been built in 1918.

Dr. Ohnstad was a member of the Red River Valley County Medical Society, the Minnesota State and American Medical Associations.

MICHAEL C. WELCH

Dr. Michael C. Welch, for many years a prominent Saint Paul physician and surgeon, died Saturday, January 30, 1943, in St. Joseph's Hospital following a long illness.

He was born on May 17, 1871, in Wilton, Wisconsin, the son of John Welch and Nora Bergen Welch, both of whom were born in Ireland.

He graduated from the University of Illinois in June, 1905, and spent two years at the Cook County Hospital as intern and house physician following which he located in Saint Paul. He gave freely of his services as a draft board examiner in World War I, then volunteered for enlistment. He was sent to Camp Grant, then overseas for eighteen months, returning with the rank of captain. He opened offices at 936 Lowry Building, which he maintained until his death.

He lived at 801 Hague Avenue, with a nephew, J. L. Welch. Surviving him are two sisters, Mrs. William Welch and Margaret Welch of Tomah, Wisconsin; a brother, James A. Welch of Saint Paul; two nieces, Mrs. Joseph M. Donahue of Saint Paul and Mrs. Cassie Reed of Joplin, Mo.; and another nephew, Ralph Welch of Van Nuys, California.

Dr. Welch was a member of the staff of St. Joseph's Hospital, a third degree member of the Knights of Columbus and a member of the Saint Paul Athletic Club, Town and Country Club, and Catholic Order of Foresters.

He possessed a quiet, retiring disposition, regarded the practice of his profession as a very serious calling and placed his services to the community above any and all other interests.

C. G. Perry

MICHAEL SULLIVAN

Dr. Michael Sullivan, who had practiced in Adrian, Minnesota, for forty-one years, prior to his retirement in 1921 when he moved to Alhambra, California, died April 19, 1943 in Alhambra.

Dr. Sullivan was born on a farm in New York state in 1852. The following year his parents moved to Wisconsin and shortly afterwards to Dallas County, Iowa.

He obtained his medical degree from the College of Physicians and Surgeons at Keokuk, Iowa, in 1878 and practiced two years at Luverne, Minnesota, before locating in Adrian.

Dr. Sullivan was appointed a pension medical examiner in 1880 by President Hayes. He served three terms as mayor of Adrian and was postmaster for four years, having been appointed by President Cleveland.

Dr. Sullivan is survived by two daughters, Mrs. Catherine Burley and Mrs. Carl C. Cowan, both of whom live in California.

VIRUS DESTROYED WITH LIGHT

Destruction by ultraviolet light of the virus type of disease germ depends on hitting a certain vital spot or "Achilles heel" of the virus, Dr. Harvey C. Rentschler, director of research at the Westinghouse Lamp Division, declared.

His statement was based on thousands of tests in which bacteriophage, a virus that destroys bacteria, was subjected to an ultraviolet light barrage.

"This ability of ultraviolet to inactivate virus," Dr. Rentschler said, "means that science now has an effective weapon to use in the battle against influenza, infantile paralysis and the common cold among other diseases thought to be caused by virus."—*Science News Letter,* April 3, 1943.

Ninetieth Annual Session

Hotel Radisson, Minneapolis

May 17, 18, 19, 1943

Registration: The registration desk on the Mezzanine floor of the Hotel Radisson will open Sunday, May 16. Members are requested to bring their membership cards.

This year there will be two sections. Section II will be held in the Flame Room and will be devoted to scientific motion pictures, except that on Monday morning the American College of Chest Physicians will hold its Regional Meeting in this room.

Luncheons: Twenty Round Table Discussion Luncheons have been arranged for Tuesday and Wednesday, May 18 and 19. Tickets must be purchased in advance for these luncheons. Lists of subjects and leaders are printed in this program and on reservation cards mailed with the program. Attendance at each luncheon is limited to 25 and late-comers will be accommodated according to their choice if limits have not already been reached. Tickets $1.00.

Annual Banquet: The annual dinner for members, guests and their wives will be held at the Minikahda Club, Tuesday, May 18, at 7:00 P. M. The Honorable Walter H. Judd, Congressman from Minnesota, and S. H. Baxter, President of the Minnesota State Medical Association, will be banquet speakers. Tickets $2.00.

Open House: All convention visitors and their wives will be guests of the Minnesota State Medical Association and the Hennepin County Medical Society at an Open House, to be held Monday night, May 17, at 7:30 P. M., on the Mezzanine Floor at the Hotel Radisson. Exhibits will be open for leisurely inspection and there will be a program of music and motion pictures.

Guest Speakers: Three societies are sponsoring visiting speakers:

The Minnesota Radiological Society is sponsoring Dr. Edward L. Jenkinson, Director of the Department of Radiology at Saint Lukes Hospital, Chicago, who will deliver the Russell D. Carman Memorial Lecture on the subject of "The Differentiation of Endometriosis and Carcinoma of the Sigmoid Colon."

The Northern Minnesota Medical Association is sponsoring the Honorable Walter H. Judd, Congressman from the Fifth District, Washington, D. C.

The Northwestern Pediatrics Society is sponsoring Dr. Frank C. Neff, Kansas City, Kansas.

Minnesota Academy of Ophthalmology and Otolaryngology: The Academy will sponsor the Symposium on "Eye, Ear, Nose and Throat Diseases for the General Practitioner," Tuesday, May 18, at 11:00 A. M., in the Gold Room. A program of Case Reports by Minneapolis members has also been arranged by the Academy for Tuesday, May 18, 2:00 to 4:00 P. M., in the Spanish Room. Both are open to all convention visitors. The Round Table Luncheon on "Treatment of Acute Infections of the Nose and Sinuses," scheduled for Tuesday, May 18, at 12:15 P. M., is also sponsored by the Academy and is open to all visiting physicians within the attendance limit set for Round Table Luncheons.

Child Health in Wartime: A special Conference on Child Health and Welfare Problems in Wartime will conclude the program, Wednesday, May 19, 2:00 to 4:00 P. M. Nurses, nutrition workers, social welfare workers and members of Parent-Teacher Associations will be invited to attend this session.

Medal: The Southern Minnesota Medical Association will present its annual medal for the best scientific exhibit presented by an individual physician at this meeting. Presentation will be made at the Banquet, Tuesday evening, May 18, at the Minikahda Club.

Fifty Club: This year's candidates for election to Minnesota's "Fifty Club" will be honor guests of the Association at the 90th Annual Banquet to be held Tuesday, May 18, at 7:00 P. M., at the Minikahda Club. Presentation of lapel buttons and certificates to candidates will be a feature of the Banquet program.

Woman's Auxiliary: Wives of physicians attending the meeting may secure programs of business and social sessions of the Woman's Auxiliary at the Women's Registration Desk in the Lobby of the Hotel Curtis. All visiting women are cordially invited to attend the special events arranged by the hostesses of the Hennepin County Medical Society Auxiliary.

Medical Women's Luncheon: A luncheon meeting for all women physicians will be held Monday, May 17, at 12:15 P. M. Reservations for the luncheon should be made direct to Dr. Nora M. C. Winther, Vice President, Minnesota Branch, American Medical Women's Association, 1450 Medical Arts Building, Minneapolis.

University of Minnesota Alumni: University of Minnesota alumni will hold their annual reunion at a cocktail hour to be held at 5:00 P. M., Tuesday, May 18, at the Minikahda Club before the Annual Banquet. All University alumni are invited to attend.

Golf: The annual Golf Tournament of the Minnesota State Medical Association will be held Sunday, May 16, at 1:00 P. M., at the Minikahda Club, Minneapolis. Attractive prizes have been donated. All medical golfers are urged to enter. Registrations should be made in advance on the enclosed card to L. R. Boies, Minneapolis.

SCIENTIFIC PROGRAM
HOTEL RADISSON

Monday, May 17, 1943

SECTION I—GOLD ROOM

A. M.

9:00 **Fracture Symposium**
Compression Fractures of the Spine—C. C. Bell, Saint Paul
Intertrochanteric Fractures of the Hip—M. O. Henry, Minneapolis
Ununited Fractures—M. S. Henderson, Rochester
Injuries of the Urinary Tract Complicating Fractures of the Pelvis—T. H. Sweetser, Minneapolis

11:00 **Fracture Symposium (Continued)**
Fractures and Dislocations of the Carpal Bones—E. R. Anderson, Minneapolis
Fractures of the Lower End of the Radius and Ulna—C. C. Chatterton, Saint Paul
Discussion

P. M.

2:00 **Care of the Aged**
General Management—J. F. Norman, Crookston
Nutritional Needs—E. L. Tuohy, Duluth
Surgery—O. T. Clagett, Rochester
Discussion

4:00 **Russell D. Carman Memorial Lecture**
The Differentiation of Endometriosis and Carcinoma of the Sigmoid Colon
Edward L. Jenkinson.....Chicago, Illinois
Associate Professor of Radiology, Northwestern University, and Director of the Department of Radiology, St. Lukes Hospital, Chicago

SECTION II—FLAME ROOM

A. M.

9:00 **American College of Chest Physicians, Regional Meeting**
Bronchiectasis—H. C. Hinshaw, Rochester
Bronchial Tuberculosis—R. J. Davies, Nopeming
Experiences in a Program for the Control of Pulmonary Tuberculosis in Chicago—Richard Davison, Chicago, Illinois
Secretary to the Board of Directors, Chicago Municipal Tuberculosis Sanitarium

11:00 **American College of Chest Physicians, (Continued)**
Silicosis
A. E. Russell.....New York, City
Senior Surgeon, United States Public Health Service, Liaison Officer, Second Service Command, Governor's Island
Discussion

P. M.

SCIENTIFIC CINEMA

2:00 **Inguinal Hernioplasty**
Medical Film Guild

2:30 **Tendon Injuries**
R. K. Ghormley.....Rochester

4:00 **Postpartum Hemorrhage**
J. B. De Lee.....Chicago
(This film was completed just before the author's death in April, 1942)

Tuesday, May 18, 1943

SECTION I—GOLD ROOM

A. M.

9:00 **Abnormal Uterine Bleeding**
In Adolescence—Nora M. C. Winther, University of Minnesota
In Pregnancy—F. J. Schatz, St. Cloud
In the Menopause—L. M. Randall, Rochester

11:00 **Eye, Ear, Nose and Throat Diseases for the General Practitioner**
Diagnosis of Glaucoma—A. G. Athens, Duluth
Industrial or "Shipbuilders'" Kerato-Conjunctivitis—K. C. Wold, St. Paul
Foreign Bodies in Food or Air Passages—K. A. Phelps, Minneapolis
Discussion

12:15 **Round Table Luncheons**

P. M.

2:00 **Cardiovascular Disease**
Coronary Disease—A. R. Barnes, Rochester
Hypertensive Heart Disease—G. E. Fahr, Minneapolis
Psychosomatic Aspects of Hypertension—W. H. Hengstler, St. Paul
Medical Management of Early Cases of Hypertension—S. G. Sax, Duluth

4:00 **Practical Applications of a Routine Blood Count in the Newborn with Special Reference to the Obstetrical Nursery**
Frank C. Neff.....Kansas City, Kansas
Professor of Pediatrics and Head of Department, School of Medicine and Children's Hospital, University of Kansas

SECTION II—FLAME ROOM

A. M.

SCIENTIFIC CINEMA

9:00 **Myasthenia Gravis**
L. M. Eaton.....Rochester
O. T. Clagett.....Rochester

9:45 **Fascia Lata in Repair of Hernia**
J. M. Hayes.....Minneapolis

11:00 **Peptic Ulcer**
E. D. Kiefer.....Boston

12:15 **Round Table Luncheons**

P. M.

SCIENTIFIC CINEMA

2:00 **A Clinic on Sigmoid Sinus Thrombosis**
Medical Film Guild

2:40 **Vaginal Hysterectomy**
J. M. Waugh.....Rochester

4:00 **Pharmacology of Respiratory Stimulants**
Medical Film Guild

7:00 **Annual Banquet.....Minikahda Club**

Wednesday, May 19, 1943

SECTION I—GOLD ROOM

A. M.

9:00 **Newer Therapeutics in Surgery**
Use of Sulfonamides in Abdominal Surgery—C. E. Rea, Saint Paul
Use of Dicumarol—N. W. Barker, Rochester
Use of Blood and Blood Substitutes—
J. E. Blumgren.....Duluth
M. G. Gillespie.....Duluth
Discussion

11:00 **Control of Tropical Diseases**
Captain E. G. Hakansson (MC)..U. S. Navy

12:15 **Round Table Luncheons**

P. M.

2:00 **Child Health in Wartime**
Feeding the Child—R. E. Nutting, Duluth
Preparing the Child for School—Jeannette Baker, Fergus Falls
Emotional Problems of Children—H. F. Helmholz, Rochester
Caring for Children of Working Mothers—J. A. Anderson, Minneapolis
Juvenile Delinquency—H. B. Hanson, University of Minnesota

SECTION II—FLAME ROOM

SCIENTIFIC CINEMA

A. M.

9:00 **Nonoperative Treatment of Paranasal Sinusitis**
Medical Film Guild

9:30 **Otitis Media in Pediatrics**
Medical Film Guild

11:00 **Skin Grafting**
A Demonstration of Technique Especially Adaptable to the Resurfacing of Granulating Areas by Use of the Padgett Dermatone—H. O. McPheeters, Minneapolis

12:15 **Round-table Luncheons**

P. M.

2:00 **Child Health in Wartime**

(See Program in Section I)

Protection of the health and well-being of children is the most urgent of all wartime civilian health problems. For that reason, the program for Wednesday afternoon, May 19, will be devoted entirely to the subject, "Child Health in Wartime." Public health nurses, social welfare workers, members of Parent-Teacher Associations and all others especially interested in child health are invited to attend this session with the physicians.

SCIENTIFIC EXHIBITS

S-9 **American Medical Association**
Tularemia—Spread and Control
Tularemia—Pathology

S-3 **Committee on First Aid and Red Cross**
J. S. Lundy, Chairman, Rochester

S-1 **Mayo Clinic and Mayo Foundation**

S-4 **Minnesota Public Health Association**
E. A. Meyerding, Executive Secretary, Saint Paul

S-10 **Minnesota Society for the Control of Cancer**
Mrs. S. E. Linsley, Executive Secretary, Saint Paul

S-2 **Minnesota Society for the Prevention of Blindness**
F. E. Burch, Secretary, Saint Paul

S-7 **Minnesota State Department of Health**
A. J. Chesley, Secretary and Executive Officer, Saint Paul

S-8 **The Surgical Aspect of Strabismus**
W. H. Fink, Minneapolis

S-6 **Tuberculosis Control in Minnesota**
Committee on Tuberculosis
J. A. Myers, Chairman, Minneapolis

S-11 **University of Minnesota**
Department of Ophthalmology
University of Minnesota
University Press

S-5 **War Injuries of the Face and Jaws and Fractures of the Facial Bones**
C. W. Waldron, Minneapolis

Exhibits and Demonstrations will be open daily at 8:00 A. M., during the intermissions and preceding the afternoon sessions.

Round-table luncheon discussions will be held Tuesday and Wednesday. Reservations should be made in advance.

WOMAN'S AUXILIARY

Mrs. Raymond J. Josewski, *President*
Stillwater, Minnesota
Mrs. W. H. Rucker, *Publicity Chairman*
Minneapolis, Minnesota

ANNUAL CONVENTION
May 17-18-19, 1943
Headquarters—Radisson Hotel, Minneapolis, Minn.

Monday, May 17

8:00 a.m.—Registration—Radisson Hotel
10:00 a.m.—Executive Board Meeting followed by Luncheon at 1:00 p.m.—Curtis Hotel (Board members only)
3:30 p.m.—Tea—Medical Arts Building—20th Floor All visiting women are invited as guests of Hennepin County Medical Auxiliary

Tuesday, May 18

8:00 a.m.—Registration—Radisson Hotel
10:00 a.m.—Annual Meeting—followed by Luncheon at 1:00 p.m.—Curtis Hotel—Open to all members. Musical program following
Post-convention board meeting immediately following luncheon program

Wednesday, May 19

10:00 a.m.—12 noon
Final get-together—all members invited
Medical Arts Lounge—20th Floor
Guests of Hennepin County Medical Auxiliary.

Committee chairmen for the annual meeting are:
General Arrangements—Mrs. Joseph M. Hall; co-chairman, Mrs. Frederick H. K. Schaaf.
Registration—Mrs. Walter K. Haven
Hospitality—Mrs. William B. Roberts; co-chairman Mrs. James M. Hayes
Publicity—Mrs. William R. Jones; co-chairman, Mrs. William H. Rucker
Flowers—Mrs. John F. Curtin
Music—Mrs. Harold F. Wahlquist
Tickets—Mrs. David D. Anderson
Tea Arrangements—Mrs. Samuel B. Solhaug
Annual Luncheon—Mrs. Edward A. Regnier

Hennepin County Medical Auxiliary extends a hearty welcome to auxiliary members throughout the state

Ramsey County

Presidents and secretaries of all Saint Paul women's clubs were invited to the Public Relations Tea given by Ramsey County Medical Auxiliary, March 29, in the club rooms of the Medical Arts Building in Saint Paul.

Mrs. Arnold Gruenhagen, an auxiliary member, who is chairman of the speakers' bureau of the Ramsey County Red Cross, explained the work of her group.

Mrs. W. H. Von der Weyer and Mrs. E. C. Eshelby of the Civilian Defense Council told of Ramsey's participation in that branch of war work.

The entertainment of the afternoon was a charming book review by Mrs. Joy Jones entitled "Old Soldiers Never Die." A simple yet lovely tea completed an afternoon that Ramsey visitors will long remember.

Washington County

A twenty-five-dollar cash prize has been awarded Washington County Medical Auxiliary in the National Hygeia Contest. Mrs. D. Kalinoff, Stillwater, was the Washington County chairman. Heartiest congratulations for such splendid endeavor.

Minnesota Academy of Medicine

Meeting of February 10, 1943

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, February 10, 1943. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the President, Dr. H. B. Zimmermann.

There were thirty-six members and one guest present.

Minutes of the January meeting were read and approved.

There being no old or new business to come before the Academy, the scientific program followed immediately.

TRANSIENT INFILTRATION OF THE LUNG PARENCHYMA ASSOCIATED WITH EOSINOPHILIA

EVERETT K. GEER, M.D.
Saint Paul, Minnesota

Dr. Everett K. Geer, of Saint Paul, presented a case report on the above subject. It was of interest because it simulated tuberculosis as the involvement was in the upper lobes. The clinical course in the hospital was afebrile and complete recovery occurred without any specific therapy for her allergic conditions.

(This and another similar case will be published in MINNESOTA MEDICINE at a later date.)

Discussion

DR. ERLING W. HANSEN (Minneapolis): I have been very much interested in this matter of allergy, and I think Dr. Condit is very much in order when he brings that into the picture. We have been too prone, in the past, to think that eosinophilia occurred only with such conditions as trichinosis. In our department of Eye, Ear, Nose and Throat, there is no question but what eosinophilia is of importance in several conditions. Not having looked up the subject beforehand, but remembering very distinctly swellings such as occur in the vasomotor reactions in allergic nasal difficulties of asthma, and the soft swellings in the lids and conunctivæ in hay fever and inhalant sensitivities and others like spring catarrhal conjunctivitis, we know that not only in smears but also in the blood picture there is a very definite eosinophilia. In looking back some time ago into the subject of migraine as it ties up with the question of allergy, a very striking illustration of what can happen, a marked swelling with edema of the brain, is reported in the *Journal of Allergy* about 1936 by Goltman.

The patient was a nurse who had such terrific headaches that a decompression was performed. Following this, she had a marked herniation of the brain in the decompression area every time she had these headaches. And not until then was she studied from the standpoint of allergy. She was getting the reaction from wheat. If you can have that much reaction in the brain, I suppose it is possible to have just as much reaction in the nose, bronchial tree, with infiltration of the lung; and it does seem that this transient lung picture possibly fits in here.

DR. ALFRED HOFF (Saint Paul): Was there anything in this case that might suggest peri-arteritis nodosum?

DR. H. B. ZIMMERMANN (Saint Paul): I recently saw a man with what I think might have been intestinal obstruction, with cramp-like pains coming on at various times. This was always followed by a high eosinophilic count and we took it to be an allergic reaction.

DR. GEER (in closing): I want to thank the gentlemen who have discussed this report. In answer to Dr. Hoff's question—aside from the asthma and eosinophilia, the complaint which suggested peri-arteritis nodosum was the discomfort in the left leg which needed close questioning as to whether it was pain or numbness. The muscle biopsy was done with arterial changes in mind and also trichinosis.

I suspect this condition is more common than we know. Shortly after this woman left the hospital I saw in consultation another woman at Midway Hospital who had been ill about two months, with an asthmatic onset with a shifting parenchymal involvement and an eosinophilia. She, however, had prolonged fever but recovered.

It should be emphasized that this is a benign condition though the illness may be protracted. As far as I know, no deaths have occurred.

DR. ZIMMERMANN: Do you consider this an allergic condition?

DR. GEER: That is the present-day conception.

INJURY TO SPINAL CORD AND MENINGES FROM SPINAL ANESTHETIC

GORDON R. KAMMAN, M.D.
Saint Paul, Minnesota

Dr. Gordon Kamman, of Saint Paul, gave a paper on the above subject. Dr. A. B. Baker, University of Minnesota (by invitation), gave the pathological report on the case.

Abstract (Dr. Kamman)

A case is reported in which a sixty-six-year-old male was given a spinal anesthetic of metycaine to facilitate the suprapubic removal of an hypertrophied prostate. Patient never recovered sensation or motor power of lower extremities and died of a cerebral accident seven months later.

Abstract (Dr. Baker)

Pathological examinations of the spinal cord revealed an extensive chronic inflammatory membrane involving all layers of the meninges and completely obliterating both the subdural and subarachnoid spaces in the lower thoracic and upper lumbar segments of the cord. At these same levels, the cord itself showed an extensive damage to the posterior columns.

In the higher cord segments only the ascending columns of Gall were demyelinated.

Discussion

Dr. E. M. Hammes (Saint Paul): I want to congratulate Dr. Kamman on this interesting report, and also Dr. Baker on the beautiful pathological specimens. There seems to be considerable difference of opinion as to what produces the serious reactions following spinal anesthesia. Viers, referring to novocaine, states that none of the complications encountered is due to this anesthetic or the method but either to inaccuracies in the dosage or due to poor technique. Lunde suggests that many of the accidents following spinal anesthesia in man are due to factors other than the action of the anesthetic agent and that it seems probable that when paralysis follows the use of ordinary doses of spinal anesthetic, the spinal cord was previously diseased. Dr. Davis and his co-workers, on the other hand, believe that all spinal anesthetics are both hemolytic and myelitic. I have had an opportunity to study eight such cases. Five were patients who had preëxisting neurological diseases. It is a well-recognized fact that patients with preëxisting neurological diseases should not be given a spinal anesthetic. It may rarely be justifiable when the surgical condition is an acute one where the physician does not have sufficient time and opportunity to study the patient neurologically. I think it is very important that at least a superficial neurological examination be made on every patient before a spinal anesthetic is given to exclude any preëxisting neurological disease. Light and his co-workers, in the January, 1940, issue of *Surgery*, summarize over 60,000 cases and emphasize the various neurological complications.

Dr. E. K. Geer (Saint Paul): I would like to ask Dr. Kamman if this problem has been approached on the basis of idiosyncrasy or allergy? Has any one done any skin testing with the various drugs used for spinal anesthesia?

Dr. L. W. Barry (Saint Paul): Does this come from lumbar puncture also, or do we get it when administering spinal anesthetic?

Dr. Hammes: I would appreciate it if Dr. Baker would advise us what the condition of the blood vessels was in the pia arachnoid.

Dr. F. F. Callahan (Pokegama): Could this be the result of infection?

Dr. R. T. La Vake (Minneapolis): It seems to me that the directional tendency of this interesting and important paper must be met with balance. First, may I ask Dr. Kamman if he feels that we should not use spinal anesthesia? He did not say so, and likely feels as I do that there is relative danger in the use of any anesthetic and the best we can do is to decide which anesthetic is the least dangerous under conditions present.

We have tested practically every type of anesthesia on our service at the Minneapolis General Hospital. We have had lethal ether inhalation pneumonias, but, as chance would have it, have never had difficulty with spinal anesthesia. The few tragic consequences of spinal anesthesia that I have seen in various clinics have made me avoid spinal anesthesia unless in consultation the majority believed it to be the least dangerous in that particular case.

Dr. J. A. Lepak (Saint Paul): I would like to ask Dr. Kamman whether in these cases there was good anesthesia—did the patient take it well and was the surgeon satisfied with the anesthesia?

Dr. H. B. Zimmermann (Saint Paul): In answer to Dr. La Vake's question, I think the usual anesthetic hazards—embolism, thrombosis, pulmonary complications—are just as likely to happen (because of the lowering of blood pressure) after spinal anesthesia as after inhalation anesthesia.

Dr. Kamman (in closing): So far as I can find out I don't think that technique has anything to do with it. Some men, in reviewing possible causes, say technique has something to do with it. There have been many cases reported where the technique was faultless as possible, and poor results obtained. There was no inflammatory reaction in the spinal cord or meninges in this particular case. A degenerative process takes place which, to my way of thinking, is irreversible in some cases.

Answering Dr. Geer, I think there is an idiosyncrasy; so far as I know, no patch tests have been made.

Answering Dr. Barry, lumbar puncture itself has never caused changes of this kind.

Answering Dr. Callahan, this is not an infectious process.

Answering Dr. La Vake, it is a question of balance. There is risk in all anesthetics. I think we do have to remember that there are thousands of cases in which spinal anesthetic is used without any trouble.

Answering Dr. Lepak's question—was anesthesia satisfactory? not in the last case; they had to give him cyclopropane in order to remove the appendix.

Answering Dr. Condit, I don't think hypertension has anything to do with it.

Dr. A. B. Baker (University of Minnesota) (by invitation): In this case there were no vascular changes. Some of the vessels were constricted by the membrane but none of the vessels was completely occluded. Dr. Bieter, at the University, used spinal anesthetic in rabbits; he collected the spinal cords for a study. About six months ago these cords came to my attention. We found whenever a rabbit got satisfactory spinal anesthesia every cord showed tissue damage. We can't always judge actual anatomic damage by clinical observations alone since in rabbits one may get damage to the spinal cord tissue and yet the animals seem normal in every respect.

Dr. La Vake: I would like to ask Dr. Baker if in his experiments the cords were compared with a large series of cords from apparently normal animals? When this is done in experiments with drugs affecting the liver, one often finds pathology in apparently normal animals that makes it very difficult at times to interpret similar findings, as regards cause and effect after the use of experimental drugs.

Dr. Baker: In all our experimental work we have control animals which are maintained along with the experimental rabbits. We never have found this change in the normal cords.

Dr. F. E. B. Foley (Saint Paul): The first case reported by Dr. Kamman was the case of a man under my care for prostatic obstruction. Actually two injections of the spinal anesthetic solution were given at the time of the suprapubic prostatectomy. One hundred forty mgms. of metycaine in 3.2 c.c. of fluid were first given. This did not give anesthesia sufficiently high for the operation. In twenty minutes or half an hour, a second injection of 100 mgms. of metycaine in 2.25 c.c. of fluid was given. This gave satisfactory anesthesia.

Dr. Kamman has described the permanent motor and sensory loss which ensued. In another case I gave a metycaine spinal anesthetic using 120 mgms. of the drug in even greater dilution. The same injury, in less pronounced degree, resulted. I have seen other less

significant sensory and motor changes with apparent full and complete recovery.

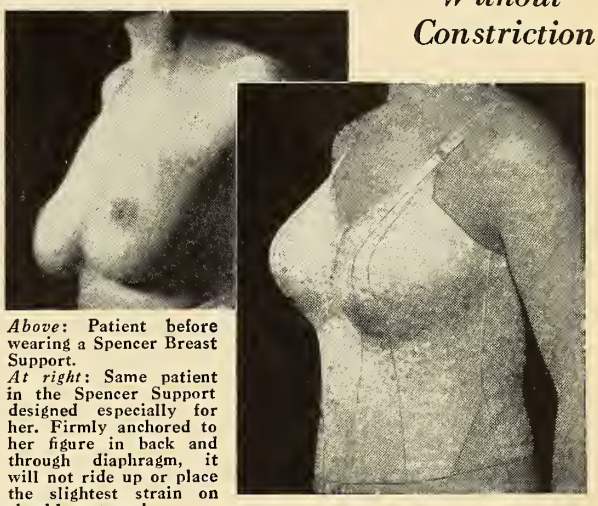
The experience at the Miller Hospital, where we have had three cases of severe and permanent injury among several thousand anesthesias, convinces me that the particular drug used is an important and determining factor. In all three of these cases metycaine was used. So far as I know, there has not been in the Miller Hospital a case of ill-effect from any of the other spinal anesthetics.

The Miller Hospital experience—plus the 66,000 spinal anesthesias with exceedingly small incidence of permanent ill effects mentioned by Dr. Kamman—is pretty convincing evidence that the drug used and individual idiosyncrasy are the determining factors. As an explanation for the ill effects, I take no stock at all in faults of technique as suggested by some specialists in anesthesia. All of our spinal anesthesias are done in a routine way. After so many of them, there is confidence it is a competent way. The particular drug used plus individual idiosyncrasy are more reasonable explanations than faults of technique.

For several years I have used 2 per cent metycaine solution for local urethral anesthesia in the male. For several years this went on day in and day out without the occurrence of any untoward effect whatever. Then, one day about six months ago a very severe reaction with near fatality occurred. I am confident that nothing but individual idiosyncrasy can explain that occurrence.

The meeting adjourned.

E. V. KENEFICK
Secretary



QUININE NEEDED TO TREAT MALARIA

A plea for physicians of the United States to turn in to the National Quinine Pool all supplies of quinine is contained in *The Journal of the American Medical Association* for March 13. *The Journal* says:

"Every physician is urged to contribute to the National Quinine Pool all supplies of quinine and other cinchona salts and alkaloids not absolutely essential in his practice for the treatment of malaria. These compounds are needed to maintain an adequate stockpile of antimalarial agents for use in the armed forces. Although synthetic substances such as atabrine are being produced in enormous quantities and are used wherever possible, there are many conditions for which the drug of choice is quinine. Until the war is over little cinchona bark of good quality will be forthcoming. The currently available barks from South America are of a low grade and sufficient only for the manufacture of totaquine, which is satisfactory for domestic use. The provisions of conservation orders M-131 and M-131A essentially restrict the sale, transfer, delivery or use of quinine salts and alkaloids to the treatment of malaria. Quinidine is an exception which may be used in the treatment of certain heart conditions. Such restrictions will permit physicians to contribute unused and opened quinine supplies to the National Quinine Pool, care of the American Pharmaceutical Association, 2215 Constitution Avenue, Washington, D. C. Each package received will be tested for identity, pooled and assayed. The less common salts will be processed to quinine sulfate or hydrochloride. The materials needed are bulk cinchona salts and alkaloids, tablets, capsules and pills; quinine, quinidine, cinchonine and cinchonidine. Do not send preparations of quinine or other cinchona derivatives in combination with other medicinal agents; ampules and parenteral medication; liquid preparations or quinine and urea hydrochloride, quinine and urethane, quinine bismuth iodide, elixir iron, quinine and strychnine and similar preparations. The armed forces need all available quinine. Any contribution, no matter how small, will be useful; the need is urgent."

DEFINITE UPLIFT FOR THE HEAVIEST PTOSED BREASTS!

This Spencer Support Holds Breasts in Natural Position Without Constriction

Above: Patient before wearing a Spencer Breast Support.
At right: Same patient in the Spencer Support designed especially for her. Firmly anchored to her figure in back and through diaphragm, it will not ride up or place the slightest strain on shoulder straps!

IMPROVES CIRCULATION of the blood through the breasts, lessening the chance of the formation of non-malignant nodules, and improving tone.

PROVIDES COMFORT AND AIDS BREATHING when worn by women who have large ptosed breasts.

AIDS MATERNITY PATIENTS by protecting inner tissues and helping prevent outer skin from stretching and breaking.

HELPS NURSING MOTHERS by guarding against caking and abscessing.

Individually designed for each patient.

Spencer Supports are never sold in stores. For a Spencer Specialist, look in telephone book under "Spencer Corsetiere" or write us direct.

SPENCER *INDIVIDUALLY DESIGNED*

Abdominal, Back and Breast Supports

SPENCER INCORPORATED,
137 Derby Ave., New Haven, Conn.
In Canada: Rock Island, Quebec.
In England: Spencer (Banbury) Ltd., Banbury, Oxon.

May We Send You Booklet?

Please send me booklet, "How Spencer Supports Aid the Doctor's Treatment."

Address O-5

KARO Red Label and Blue Label are equally effective in MILK MODIFICATION

The chemical compositions and caloric values of these two types of KARO are practically identical.

Therefore the slight difference in flavor (hardly noticeable in the milk mixture) in no way affects the value of KARO as a milk modifier.

Either type may be prescribed for prematures, newborns and infants.

How much KARO for Infant Formulas?

The amount of KARO prescribed is 6 to 8% of the total quantity of milk used in the formula—one ounce of KARO in the newborn's formula is gradually increased to two ounces at six months.

REPORTS and ANNOUNCEMENTS

COURSE IN ELECTROCARDIOGRAPHY

The Michael Reese Hospital in Chicago offers a tw weeks' full-time, intensive course in electrocardiograph from August 16 to August 25, 1943, under the direc tion of Dr. Louis N. Katz. Instruction will be give on the construction and use of the electrocardiograp machine, its operation and the interpretation of th cardiogram itself. The fee for the course is $100.0(For further information address Michael Reese Hos pital, Cardiovascular Department, 29th and Ellis Ave nue, Chicago, Illinois.

CONTINUATION STUDY COURSES

The courses offered during May and June in medi cine, hospital service and public health at the Cente for Continuation Study, University of Minnesota, in clude the following:

May 14-16—Radiology
May 17-19—Homes for the Aged
May 17-22—Kenny Technique
May 20-22—Obstetrics (Nurses)
June 1-3—Tuberculosis (Nurses)
June 1-5—Kenny Technique
June 7-12—Obstetrics and Pediatrics
Arranged—Dermatology and Syphilology

Courses completed in April and the first week of Ma included: Cancer Education, Kenny Technique, Com municable Diseases (Nurses), Electrocardiography, Ob stetrics, and Refraction.

Application blanks for registering in these course will be sent upon request from the enter for Continua tion Study, University Campus, Minneapolis, Minnesota

JOURNAL-LANCET LECTURE

The Third Annual Journal-Lancet Lecture in th Medical School of the University of Minnesota will b delivered by Professor Ernst Gellhorn, M.D., of th Medical School of the University of Illinois. The lec ture will be delivered at 8 p.m., Wednesday, May 19 1943, in the Amphitheater, Room 15, of the Medica Sciences Building of the University. Professor Gell horn's subject will be "Experimental Studies on Con ditioned Reactions and Their Implications for Medi cal Problems."

Professor Gellhorn has made particularly importan contributions to the study of specific physiologica disorders in patients with nervous and mental diseases He has been a pioneer in the endeavor to bring psy chiatric problems into the scope of study by physiologi cal methods.

Of General Interest

Dr. Emmett R. Samson of Stillwater has joined the Navy as Lieutenant Commander and has been stationed at San Diego, California, since April 5.

* * *

Dr. William W. Moir of Minneapolis paid a brief visit to Stillwater the early part of April. He still carries some of the shrapnel acquired during his visit in North Africa.

* * *

Dr. John S. Lundy of Rochester gave the Ether Day address in honor of Crawford W. Long at the University of Georgia on March 30. His paper was entitled "One Hundred One Years of Anesthesia."

* * *

Dr. H. E. Bowers of Lake City is in Vancouver, Washington, visiting his son, First Lieutenant Robert Bowers, who is with the Army Medical Corps at Barnes Hospital. During Dr. Bowers' absence Dr. W. J. Cochrane, who returned from Beverley Hills, California, in April, will be in charge of Dr. Bowers' practice.

* * *

The National Foundation for Infantile Paralysis has made a five-year grant totaling $150,000 to the Yale University School of Medicine for the establishment of a Yale Poliomyelitis Study Unit. A Yale Poliomyelitis Commission was established in 1931 by Drs. James D. Trask (now deceased) and John R. Paul. This grant will place the work of this commission on a more permanent basis.

* * *

At a special business meeting of the Wabasha County Medical Society held at Buena Vista Sanatorium, Wabasha, Minnesota, April 14, Dr. Louis A. Buie of Rochester, Councilor for the First District, an invited guest, gave a talk on various pertinent activities of the Minnesota State Medical Association. Also he showed several reels of the colored motion pictures which he has taken through the proctoscope. In these pictures he demonstrated various lesions of the colon.

Lt. Leonard J. Monson of Canby, a member of the Naval Reserve, entered active service in October. Accompanied by his family he motored to San Diego and in January left for duty with the Pacific fleet. He may be reached by a letter addressed to L. J. Monson, Lt. (MC), USNR, Headquarters Squadron, Sec-

Greetings to Minnesota Physicians!

May we welcome you to Minneapolis and extend the wish that your 1943 Convention will be the greatest on record.

ond Marine Aircraft Wing, FMF, c/o Fleet Postmaster, San Francisco, California. His family has returned to Canby.

* * *

Mrs. Anne Wesbrook, widow of Dr. Frank Wesbrook, now living at 2835 West 42nd Avenue, Vancouver, B. C., writes as follows concerning the article written about her husband by Dr. Edward L. Tuohy of Duluth, which appeared in the January, 1943, number of MINNESOTA MEDICINE:

"I have waited twenty-five years to read what I thought was an adequate appreciation of my good man—and at long last I have read it. It satisfies me completely, so to you goes my very grateful thanks. To me it is a very beautiful thing that even with the lapse of years his friends still can feel the thrill as they did when he was with them."

Mrs. Wesbrook's daughter, Helen, and her two children are with Mrs. Wesbrook while Helen's husband, George Robertson, is serving in England with the British Artillery. Mr. Robertson is in charge of an anti-aircraft unit.

* * *

MEDICAL AND SURGICAL RELIEF COMMITTEE

Formed in August, 1940, this committee is putting on a nation-wide campaign to collect surgical and medical supplies for needs in Greece, Free French forces in Equatorial Africa, Royal Norwegians in Iceland, China, Russia and in America. At present primary consideration is being given the U. S. Coast Guard, the Amphibious Forces of the U. S. Atlantic Fleet, the U. S. Maritime Commission and first aid posts, needy hospitals and other recognized relief agencies in the United States and Alaska. One of the outstanding projects is the supply of medical field sets to the medical directors of civilian defense regions. Each set consists of two portable cases equipped with instruments and supplies which are being placed in hospitals and first aid posts for use by doctors and nurses.

Fishing tackle is especially desired for the equipment of kits for use by those who possibly may be stranded at sea when the ability to catch fish may be life saving.

The Committee earnestly requests donations of medical and surgical instruments, drugs, in the form of samples or otherwise, and cash. Cash contributions may be designated for special use. Physicians, pharmaceutical houses, hospitals, and drugstores are contributing.

A sub-committee for Minnesota is headed by Dr. Claude C. Kennedy, 807 Physicians and Surgeons Building, Minneapolis. Other members are Dr. Gilbert Thomas, Dr. Alice Fuller, Dr. E. C. Robitshek, Dr. Owen Wangensteen of Minneapolis; Dr. Walter R. Ramsey, Dr. Walter Brodie, Dr. Robert Rosenthal and Dr. W. R. McCarthy of Saint Paul; Dr. H. C. Johnson of Mankato; Dr. Donald C. Balfour, Dr. Wm. R. McCarty and Dr. Henry W. Meyerding of Rochester; Dr. J. F. Norman of Crookston; and Dr. Edward Bratrud of Thief River Falls. Committee members will welcome contributions.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

FLYING MEN AND MEDICINE. The Effects of Flying Upon the Human Body. E. Osmun Barr, M.D. 254 pages. Illus. Price, $2.50 cloth. New York: Funk & Wagnalls Co., 1943.

PRIMER OF ALLERGY. Warren T. Vaughan, M.S., M.D. 176 pages. Illus. $1.75, cloth. St. Louis: C. V. Mosby Co., 1943.

THE HEART IN PREGNANCY AND THE CHILD-BEARING AGE. Burton E. Hamilton, M.D., F.A.C.P., Cardiologist, Boston Lying-In Hospital, Boston, Massachusetts, and K. Jefferson Thomson, M.D., Associate Physician, Metropolitan Life Insurance Company Sanatorium, Mount McGregor, New York. 410 pages, 22 figures. Price $5.00. Boston: Little Brown and Company, 1941.

This excellent book is divided into three parts. The first portion deals with the practical aspects of the care of cardiacs throughout pregnancy, labor, delivery, and puerperium. It represents the experience and opinions of the author and his associates. The next part deals with the physiology of the effect of pregnancy on the circulation in normal women and cardiacs. The last section discusses separately the various heart diseases in women of the child-bearing age and the effect of pregnancy on the course of those diseases.

Dr. Frederick C. Irving, Professor of Obstetrics at Harvard Medical School and Obstetrician in Chief at Boston Lying-In Hospital, who has worked in close association with the authors, contributes a chapter on Delivery and Obstetrical After-Care of Cardiacs.

Dr. Hamilton has been chief of the Heart Clinic at Boston Lying-in Hospital for over twenty years, during which time more than a thousand deliveries have been accomplished under his supervision. He is certainly one of the highest authors on this special subject.

For obstetrician, internist, and general practitioner, or anyone who has to do with heart disease in pregnancy, this is an excellent book and represents an important contribution in this field.

LOUIS L. FREIDMAN, M.D.

CHEMOTHERAPY OF GONOCOCCIC INFECTIONS. Russell D. Herrold, B.S., M.D., Associate Professor of Surgery, University of Illinois. St. Louis: C. V. Mosby Co., 1943. Price $3.00.

In this work the author gives a complete list of the sulfa drugs and the evolution of each in chronological order, the history being quite complete in every detail.

He starts out stressing the diagnosis of an acute Neisserean infection—insisting on a complete history of exposure, a smear with double stain, and incidentally given an excellent technique for the double stain—also the two-glass urine test and other check-ups with which we are all familiar. He also gives a complete classification of complications to watch out for and the symptoms

as they appear in men, women and children. Incidentally, he devotes some time to non-specific urethritis.

The chapter on treatment is especially illuminating. He gives a description of each drug for both the beginning and continuation of treatment and indicates clearly the complicating dangers in the sulfa therapy, such as nausea, skin rash, microscopic hematuria.

All of this is clearly set forth so that any average practitioner by going over this volume with some degree of concentration would be very well qualified to treat such infections successfully in 99 per cent of his cases.

There is an interesting chapter dealing with individual problems totalling sixty-two cases. Concrete instances such as he lists are clearly helpful to men seeking experience from the literature, and we recommend this section very strongly to the general practitioner in getting this book.

Finally, there is an excellent bibliography attached at the termination of the work, so that those interested further can easily locate material for more detailed knowledge. E. Z. Shapiro, M.D.

MENTAL ILLNESS: A GUIDE FOR THE FAMILY. Edith M. Stern with the collaboration of Samuel W. Hamilton, M.D. 134 pages. Price $1.00, New York: The Commonwealth Fund, 1942.

This is a brief but pointed book of advice to those whose friends or relatives are stricken by mental illness. It covers the time from when the illness first starts, through hospitalization, to after-care of the patient. For example, there is a very fair and useful discussion of the problem of private versus state hospitalization. The book is written by a lay person with professional editing and advice, and is both readable and scientifically correct. Psychiatrists spend an inordinate amount of time talking to relatives of mental patients, and this situation could be improved by a wide circulation of a book like this: a thing which unfortunately is unlikely to occur. A. S. Nissen, M.D.

ATLAS OF OVARIAN TUMORS. Gemma Barzilai, M.D. 261 pages. Illus. spiral binding. $10.00. New York: Grune and Stratton, 1943.

Two books have appeared on this subject recently. The author of this book takes up the various tumors according to the structures from which they arise, namely those that arise from the Graafian follicle, those that can be traced back to development of the otherwise dormant male gonad, and so on. He does not take up the retention cysts, because he does not regard them as neoplastic growths; but on the other hand, he seems to have omitted a presentation of what we know as the proliferating cystadenoma.

Instead of placing a caption at the head of each new paragraph, the author designates the subject matter of the paragraph by notations in the margin. As regards the illustrations of the microscopic pictures, he presents a great many pictures of the same tissue, but under higher magnification. Many of his reproductions of this kind are in color. The subject matter is presented in a very entertaining manner, and I must say the paper of the book is of unusually good quality.

A. G. Schulze, M.D.
